In further distancing himself from the Court, Powell stated that restrictions on First Amendment rights must be "applied in light of the special characteristics of the . . . environment" (Id., quoting from Tinker v. Des Moines School District, 393 U.S. 503). It was the same position that the Court had considered in deciding Martinez. Thus, Powell was relying on the strict scrutiny test established by Martinez. Yet, according to the Supreme Court, the lower courts had applied the wrong standard to this case.

To this point in case history, the Court's decisions in Martinez, Pell and Saxbe had guaranteed little more than confusion on the part of prisoners, journalists and prison administrators alike. Though it was understood that journalists, like the public, did not have a right to interview specific inmates, it remained unclear under which, if any, circumstances inmates had access to the media. The decisions in Turner v. Safely, 482 U.S. 78, and Thornburgh v. Abbott, 490 U.S. 401, would clear up the confusion, but also declaw the strict scrutiny standard established in Martinez to protect prisoners' First Amendment rights.

In 1987, Turner took the bite out of the strict scrutiny standard by developing a "reasonably related" standard. Specifically, the Court permitted prison regulations that infringe on prisoners' constitutional rights so long as those rules are reasonably related to the penological interests of the institution, which Martinez had identified as security, order and rehabilitation (482 U.S. 78). In this case, the Court's decision meant that a Missouri prison could prohibit inmate-to-inmate correspondence based on a four-part test. For a regulation to be reasonably related to a governmental interest: 1) the rule must be rationally connected with the interest; 2) there must be an evaluation of other alternatives; 3) the regulation must have an insignificant effect on the prison environment; and 4) "the absences of ready alternatives is evidence of the reasonableness of a prison regulation" (Id., at 89-90).

The decision in Turner was applied to Abbott in 1989. The prisoners in Abbott challenged the constitutionality of prison regulations that censored incoming publications. Again, the Court held that such regulations were "reasonably related to legitimate penological interests" (490 U.S. 404). The Court further explained that the cases following Martinez, including Pell and Saxbe, specifically dealt with prisoners' rights, and that in those cases, a reasonableness standard applied (Id., at 409). The split five-to-four Court went on to say that Martinez tied the hands of prison administrators in a way that jeopardized safety and security at prisons. Moreover, the Court stated that Martinez was decided in favor of the inmates because outgoing mail posed on threat to the prison's security, order or rehabilitative goals (Id., at 411).

In short, the Court explained that the reasonably related standard applied to prisoners' incoming correspondence and contacts, which included media interviews. The least restrictive means test of Martinez now only applied to prisoners' outgoing mail, or an inmate's access to the media. Thus, in 1974 what seemed to be a strict standard thoughtfully designed to protect prisoners' rights, was now a bifurcated analysis that granted broad regulatory powers to administrators and left inmates with only a single guaranteed form of uncensored communication with the media -- outgoing letters.

ANALYSIS

Though the resolution of any legal challenges to Pennsylvania's and California's regulations is far down the road, it is possible to predict the outcome. Unfortunately, based on the Court's decisions, it would appear that the regulations could stand the test of the reasonably related standard established in Turner. The Court essentially balanced away prisoners' rights.

However, there remain larger issues that the Court has side-stepped in case after case. Powell addressed some of these issues in his dissents in Pell and Saxbe, but the arguments he made are the same ones put forward for centuries by scholars of democracy and the public.

Jurgen Habermas has researched and written extensively on the role of the public sphere within a capitalistic society. A tenet of his theory of "public" is openness and access. The media play a pivotal role in society by providing information to the people. Powell expressed this thought in Saxbe when he defined the media as an "agent of the public at large" (417 U.S. 863). Thus, the news media serve a specific role -- informing the public.

There is constitutional support for Habermas' theories. Benno C. Schmidt Jr., provides a constitutional perspective which asserts that the First Amendment is saturated with laissez-faire thinking. The First Amendment was a protection for the public against government. It was written by colonists who had felt the tyranny of government and who wanted to preserve the free exchange of ideas. Schmidt refers to this sense of liberty, as manifested in the Bill of Rights, as "negative controls on official power. Consequently, the First Amendment has been viewed in negative terms: a constitutional prohibition on official interference with the free play of ideas" (Schmidt p.29). It is the same principle espoused by the Court first in New York Times v. Sullivan and later in Garrison v. Louisiana. "The First and Fourteenth Amendments embody our 'profound national commitment to the principle that debate on public issues should be uninhibited, robust, and wide-open, and that it may well include vehement, caustic, and sometimes unpleasantly sharp attacks on government and public officials' " (379 U.S. 64, 74-75, quoting from 376 U.S. 254, 270).

Censorship of inmates and the subsequent lack of information transmitted to the public serves as an example of one of Habermas' harshest criticisms of the constitutional state. He argues that the constitutional state emerged from absolutism, but operated as a tool of the bourgeois to link the government with the people. Thus, the constitutional state became "an organ of the state so as to ensure institutionally the connection between law and public opinion" (Habermas p.81). In this transformation, the public sphere became what it was trying to avoid -- an arm of the government. "In accord with its own intention, public opinion wanted to be neither a check on power, nor power itself, nor even the source of all powers" (Habermas p.82). By denying prisoners' access to the news media to air their grievances, the government's actions are tacitly consented to by a public ignorant of the real facts.

Inmate interviews are so important to the press because correspondence and telephone calls are insufficient for reporting purposes. Just the opposite, confidential, face-to-face interviews with prisoners would facilitate accurate reporting by journalists. Yet, it is this type of fact-finding that Habermas states has been avoided by the constitutional state from its inception. Without openness the bourgeois constitutional state could not exist because it relied on the principle that all human beings belonged to it through informed, relevant public discourse. "The public sphere of society stood and fell with the principle of universal access" (Habermas p.85). Because prisoners retain their First Amendment rights, they rightfully should be members of the public and participate in its discourse.

Critics of Habermas also provide support of inmates' access to the news media. Kenneth Baynes argues that Habermas' writings have been surpassed by the communications revolution. The evolution of journalism and communication has left it almost impossible for everyone in the public to have access or be heard. Instead, Baynes sees free and equal public discourse as possible within a network of institutions that include the mass media, legal argumentation and legislative debate. "In this model of the public sphere responsibility for the formation and articulation of public opinion or the 'public will' is not localized within any one institutional complex . . . but is dispersed throughout a vast communicative network" (Baynes p.323). However, if Baynes' theory holds, only attorneys, who have special privileges to meet with inmates, can ensure public discourse on the issue.

Continuing in his critique of Habermas, Baynes argues that as large media conglomerates continue to absorb more newspapers and television stations, the government should act to limit

BEST COPY AVAILABLE

one-dimensional reporting. Instead of restricting the media through regulation, Baynes calls on First Amendment rights to secure "more equitable access to communication resources" (Baynes p 323).

C. Wright Mills offers a similar perspective on society, while also further explaining causes and effects of the elite-class power component. Like Habermas, Mills holds that access to the media defines which groups are heard and which groups are not. Mills argues that such "opinion-making" becomes a key element of "power-holding" and "power-getting" (Mills p 310). Thus, controlling those who are heard, as well as what they say, is at the heart of the elite's objectives.

Using Mills' theories of mass society, it is easy to apply his principles to prisoners and the media. In short, inmates represent a public in Mills' mass society that is not heard because of decisions made by the politically elite. In fact, part of Mills' definition of a public holds that an opinion "... finds an outlet in effective action, even against -- if necessary -- the prevailing system of authority" (Mills p 303-304). Thus, by definition and parallel to the logic of Habermas' writings, because prisoners are being denied access to the media, they are being denied their public status.

The revered political thinker Thomas Hobbes would likely agree with Mills and Habermas. Hobbs writes that literally every man holds some power. "The power of a man, (to take it universally,) is his present means, to obtain some future apparent good" (Hobbes p 150). He goes on to write that a person's means include his intelligence, ability and resources. For prisoners and the public alike, the media are a resource -- a resource they are denied.

CONCLUSION

Citizens have the right to free expression. As set forth by the United States Supreme Court, prisoners have rights too. Until very recently their rights were protected and prisoners, for the most part, enjoyed free expression.

This freedom of expression is important not only to prisoners as individuals, but to the public as a whole. The public includes everyone, with each person having the opportunity to become part of the public sphere. The public sphere demands something more, at the very least a commonality. This consensus is not on an issue, but on the ability to debate and discuss the issues. More importantly, the ability to debate and discuss the issues is manifest in access to the media. It follows logically that if the news media promote or at least provide a means of conveying information for public discourse, those portrayed in the news media lead the discourse. Thus, if a person, a prisoner, is denied access to lead the discourse in the media, that person is denied a position in the public sphere to debate and discuss the issue. Consequently, the public sphere immediately ceases to exist because the discussion has been limited. The rest of the public may not even realize that the public sphere has been terminated. No news is not good news. Silence, or censorship, is anti-democratic.

The Conveyance of Socioemotional Cues in Computer-Mediated Communication: A Content Analysis of Internet Relay Chat

Kimberly K. Schaefer

Department of Communication
College of Wooster

Denise Bostdorff

Computer-mediated communication (CMC) is a relatively new communication technology, yet its ability to transcend both time and geographical distance creates an increasingly important role for computers in human interaction. Text-based CMC such as that used in Internet Relay Chat (IRC) is different from face-to-face interaction in that only keyboard characters can be used to convey messages which are typically conveyed using spoken words, paralinguistic cues, and nonverbal behaviors in face-to-face communication.

This study examines how users of IRC, a well-established social form of synchronous CMC, have adapted to the narrow bandwidth of the medium. 34% of IRC messages contained textual representations of socioemotional cues such as emoticons or typographical icons commonly known as smileys, and textual representations of paralinguistic cues as well as textual references to users performing real or virtual actions. These cues not only help maintain a social environment, but also allow for the emergence of a community of users who employ the cues to help create shared meaning among IRC users. The mere fact that IRC users consider themselves to be a "community" indicates that CMC cannot be a completely impersonal form of communication.

BACKGROUND

The advent of personal computers and local computer networks interacting to form a global computer network (the Internet) has revolutionized human communication by allowing people to transcend space and time by using computers as the medium for their messages. This new communication technology of computer-mediated communication (CMC) is becoming more widely used around the world every day. Although CMC provides a new medium for communication, it does not closely resemble face-to-face interaction. In face-to-face interaction, numerous channels exist for conveying information. Such an interaction provides information through the spoken message, paralinguistic cues, and nonverbal behaviors. Text-based CMC, however, only has the use of keyboard characters to convey the same message. Because this form of CMC relies solely upon text, it is said to have fewer channels through which information can be exchanged and has a more narrow bandwidth available for exchanging information than in face-to-face interaction.

Up to this point in time, a majority of scholarly CMC research has dealt with task-oriented situations and organizational environments (Sproull and Kiesler, 1986; Nickerson, 1994; Rice and Case, 1983). This research has also been conducted primarily on asynchronous CMC such as electronic mail where messages are sent electronically between computers while the addressee is not necessarily online at the same time (McCormick and McCormick, 1992; Sproull and Kiesler, 1986; Walther and Burgoon, 1992; Nickerson, 1994; Rice and Case, 1983). Because of the focus of research on task-oriented CMC, the ever-growing realm of social CMC remains essentially unstudied. While several previous studies (Walther and Burgoon, 1992; Rice and Love, 1987; Walther, 1992) searched for socioemotional cues and relational information in task-oriented environments, social CMC environments have not been studied for these cues. Socioemotional cues contain information about the expression of emotion, the relationship between "speakers," an action, or basically any reaction to a message. In face-to-face communication, these messages are expressed through channels unavailable to CMC users. Rather than examine a task-oriented environment, this study focuses on how people using synchronous communication incorporate these cues into the text-based messages to create and maintain a social environment.

The purpose of this study is to examine how users of a well-established social form of synchronous computer-mediated communication, Internet Relay Chat (IRC), have adapted to the narrow bandwidth of the medium and are able to portray relational information in a text-based medium. Synchronous CMC is most similar to face-to-face conversation in that users are logged onto the program at the same time and interact in "real time" using the keyboard as the mode of expression.

Chatlines—also known as chats—such as IRC are only one form of CMC, but they are used primarily for social purposes. Chats are multi-user programs which allow users to log onto the program simultaneously and interact with other users who are also online. Because these programs facilitate large numbers of users, the program is divided into channels. Channels are typically used for the discussion of certain topics. Chats like IRC usually have hundreds of possible channels. Some of these channels are continually in use, while others appear for a specific discussion and disappear once the discussion is done or no users remain on the channel. In IRC, a user does not see any of the interactions on the IRC program until the user joins a channel. Once a channel is joined, the user can see the conversation on that channel and can participate in the exchange of messages. Each of these messages is preceded by the user name.

Most chat programs ask for a user name. In IRC a user name is called a nickname or a nick and can be changed at any time. The name can be up to nine characters long and is usually a meaningful representation of what the user wants other users to know about him/her since that is

542

what the user is known by during the chat session. Nicknames, like the CMC environment, conceal information about the user's appearance, social class, age, and even gender. This anonymity allows users to experiment with portraying themselves however they want to be perceived. Judgments about the user can only be made based on what is revealed. For this reason, IRC becomes an identity playground and a virtual reality.

Because of the anonymity offered by CMC and its global connections to the Internet, people are interacting with others whom they have never met in person. Outside of the business world where letters and phone calls are made to strangers as a matter of practice, social relationships are now being fostered with strangers in unprecedented numbers (Kiesler, 1987). Kiesler also notes that pen pals and ham-radio operators also make interactional connections with others who are initially strangers, but these interactions are not as easily accessible to such large numbers of people as is the case with CMC. Prior to the advent of CMC, most social correspondence and telephone conversations between individuals occurred as the result of first knowing the person in another context, usually face-to-face communication.

In addition to the infinite possibilities for portraying oneself differently, IRC is also relatively unique because it is a noncommercial form of multi-user synchronous communication which has links in many different countries across the globe. Because of the number of IRC users (the system supports several thousand users at any given time), channels are a necessity. Channels, however, are not the only way that chaos is avoided. Two measures have been instated by the using community. "Firstly, users of IRC have devised systems of symbolism and textual significance to ensure that they achieve understanding despite the lack of" a broader bandwidth in other forms of communication. "Secondly, a variety of social sanctions have arisen amongst the IRC community in order to punish users who disobey the rules of etiquette—or 'netiquette'—and [to preserve] the integrity of those shared systems of interpretation" (Reid, 1991 no pag).

METHODOLOGY

This study consists of a content analysis of sixteen IRC logs recorded between October 22 and November 4, 1995 which are used to examine how users of a social form of synchronous computer-mediated communication, Internet Relay Chat, portray socioemotional cues in a text-based environment. These excerpts were collected from four IRC channels with at least two excerpts being taken from each channel. The unit of analysis is syntactical because the logs were searched for individual symbols or types of messages that could be determined from the textual message. The total number of messages exchanged in each log was tabulated and the frequency of socioemotional cues from each of the four categories calculated.

The content categories were inductively deduced from the socioemotional cues detected in the texts with the cues being sorted into the following categories: emoticons, emotional content displayed between asterisks, usage of the /me command, and paralinguistic. Emoticons are textual icons that convey emotional states and emotional content occurring between asterisks are textualized socioemotional responses. The /me command is a faculty of IRC. When the /me command is used, the user types /me followed by a message depicting an action (Hoffman, 1995 p.45). The message appears on the screen following an asterisk with the user name followed by the message. Thus, typing /me goes to bed becomes *<username> goes to bed. The category of paralinguistic cues includes vocalizations such as um, hmm, and laughter as well as emphasis on words or phrases which is depicted through the use of capital letters, the use of multiple vowels to indicate inflection, and the use of multiple punctuation marks at the end of a message. Once the four content categories were created, the data was then quantified by counting the number of times each type of message appeared.

RESULTS

There are thousands of channels on IRC. This study only examines excerpts from four IRC channels: #lonely, #love, #hottub, and #germany. In essence, the name of a channel attempts to sum up the channel topic. Overarching channel topics, however, only give a general idea of what type of communications are appropriate on that channel. The specific discussion topics within a channel change frequently, and the actual discussion may not correspond with the channel topic which is displayed to a user joining the channel. Channel operators or "chanops" are able to change the topic on the channel at any time. Different channels, as well as different topics, influenced the number of socioemotional cues displayed during a conversation.

After examining the results from the sixteen IRC texts, it is obvious that patterns of use for all four of the categories of socioemotion occur within the IRC environment since approximately 34% of all messages exchanged contained text that fit into the categories examined. With the exception of only one text, all four categories were represented in the excerpts. Channel #lonely had the overall lowest percentage of socioemotional cues in all four categories. Even though this channel hosted two textual conversations that conveyed particularly low percentages of relational information through the cues studied (9.1% and 16.7%), the remaining texts from that channel also contained low percentages of the use of these cues. Channel #love, even though only two texts were examined, remained relatively consistent in the use of socioemotional cues (30.9% and 31.3%). The #hottub channel, however, fairly consistently contained more occurrences of emotively charged cues. Channel #germany on the other hand, displayed two rather different amounts of relational information. In both excerpts from #germany, approximately the same number of messages were exchanged, but socioemotional cues appeared 25 (17.4%) more times in the second sample. These statistics provide an overall context for the further breakdown of cues into the four categories.

Table 1 shows the frequency of occurrence of the different cues used on the four IRC channels as a whole from which data was analyzed. The number of occurrences is followed by the percentage of messages in which these cues appeared.The category of emoticons represents the number of textual icons that appeared. The /me command tells how frequently messages of personal action occurred when IRC users typed their message following the command /me. The asterisks category displays the occurrence of actions appearing between two asterisks in the IRC log. The last category, paralinguistic, shows the number of times paralinguistic cues were typed into the text. The reason that equivalent occurrences in different texts produce unequal percentages and vice versa is because each excerpt contained a different quantity of messages.

Table 1: Socioemotional Cues on Each Channel

Channel	Emoticons	/me command	Asterisks	Paralinguistic	Total
#lonely	46 (5%)	47 (5.1%)	27 (2.9%)	106 (11.4%)	226 (24.4%)
#love	42 (9.5%)	36 (8.2%)	8 (1.8%)	51 (11.6%)	137 (31.1%)
#hottub	162 (12.4%)	133 (10.1%)	51 (3.9%)	165 (12.6%)	511 (39%)
#germany	44 (14.4%)	34 (11.1%)	13 (4.2%)	36 (11.8%)	127 (41.5%)

Within these categories, paralinguistic cues or the literal typing out of laughter, pauses, and vocal emphasis occurred most frequently followed by the use of emoticons. In about half of the texts, paralinguistic cues were found most often, while emoticons accounted for the highest count in most other cases. Only in three instances did the /me command appear more times than paralinguistic cues or emoticons within any given excerpt. The display of an action between asterisks was employed significantly less than the other categories. Only in two instances did the use of asterisks surpass the use of other forms of portraying the same information. Of these two instances, one occurred only once more than emoticons and the other only appeared more frequently than the /me command messages.

The consistency with which certain conventions within IRC appeared indicates that the cues these conventions provide are important to the portrayal of socioemotional information. These cues occur in varying degrees, but must be important to the messages since they account for 34% of all of the messages examined.

DISCUSSION

Although more relational information may be shared in face-to-face interaction, this study of IRC shows that socioemotional information can still be conveyed in a synchronous text-based environment. Users of IRC employ several methods by which relational cues are incorporated into the text: emoticons, /me command, actions displayed between asterisks, and paralinguistic cues. The intent of the sender can also be understood through the context provided by previous messages. Of course, there are always misunderstandings, but these also occur in face-to-face communication. Overall, however, these conventions allow for CMC to be used for social purposes while being personal, as well.

Facial expressions are a constant source of relational information in face-to-face conversation. Since emoticons are meant to convey emotions or actions which are portrayed through facial expressions, it is not surprising that they appeared in 10.4% of all messages—the second highest percentage of messages including specific socioemotional cues. In addition to representing facial expressions, emoticons are also easy to create. Most emoticons employ only two or three different keyboard characters in their construction. That makes them easy to place at the end of the rest of a message. Because they are simple to construct and are meant to convey the information that is continual in face-to-face interaction, they become a succinct means for portraying socioemotional information in computer-mediated communication and making the interaction more personal.

Emoticons make the textual conversation more personal by expressing the emotional reaction of a sender either to the sender's own message and/or in reaction to another's message. Occasionally, emoticons comprise an entire message, but they usually conclude another written message. Some of the most common emoticons are simple smileys:

the smiley :) or =) or sometimes : > or =]
the wink ;) (denotes sarcasm)
the frown : (or sometimes : [
and sticking out one's tongue : P

Other variations also occur to present slightly different effects:
a big grin may appear as :))))))) or :):):):):)
noses may also be included using a - or a +
a left-hander may turn a smiley in the opposite direction (: or d:
a smiley may also be turned to provide a better nose (c:
Other individualized emoticons :D :O :P~ 8) !.-)]:> b:) B-)

These are only some of the numerous ways in which IRC users incorporate emotional responses into the dialogue through the use of keyboard art.

BEST COPY AVAILABLE

Depending on the nature of the conversation, the /me command is useful for conveying real or imagined actions performed by the user. The /me command can be followed by any verb. In some interactions the /me command is inappropriate because the conversation does not require a great deal of action while other interactions are conducive to the portrayal of personal action. Because the topic of discussion dictates the appropriateness of the /me command, it accounts for percentage differences within the same channel at different times. In addition, since the /me command is not always applicable, it did not appear as often as emoticons of paralinguistic cues which are appropriate in most cases observed during this study.

Here are some examples (as they appeared in the excerpts) of /me commands as they appear on IRC:

*<user> nods off
*<user> contemplates getting out her ginger snaps and milk
*<user> introduces himself to <user>
*<user> hugs <user> goodbye
*<user> tips his hat to the ladies
*<user> bends <user> over the table and gives her a good spanking
*<user> goes to the middle of the room and puts a water pistol to his head
*<user> starts floatin' in the air...
*<user> gives <user> a rose to brighten her day
*<user> pokes <user> with her nose cuz her fingers are bizzy
*<user> takes the duct tape off of <user> mouth..you can talk now
*<user> shakes the stuffin's out of his [IRC] sister
*<user> turns knob on <realname's> head that says "Sense of Humor" to the on position

As can be seen, these responses denote both actual actions of IRC users and metaphorical actions, as well as actions that would be occurring if the interaction were face-to-face. The reference to an IRC sister/brother is similar to several references made on various channels about "familial" relations among IRC users. One user was even preparing to leave Canada for a few weeks to visit his little IRC "sis" in California. It would be the second time they had met face-to-face. Although these /me command messages tend to be used to describe more complex actions, they can also state that the user performs a simple action. These /me commands that suggest hugs, a wink, or laughter, among other simple actions, can also be shown between asterisks in a longer message.

Actions displayed between asterisks tend to display a great deal of relational information since they are most frequently used to "give" different types of greetings. The most common use sends different types of hugs from the normal *hugs* to *bugglehugs* to *tacklehugpouncetickleandlick.* A more conventional form of this last action may be *Tacklehuggies* or *huggerz.* In addition to the hugs, asterisks are used to display a user waving to other users, sneezing, dancing around, and sighing, as well as smiling, winking, and laughing, which are also typically found in the other forms of socioemotional information exchange. Because most actions which are conveyed using asterisks can also be conveyed through emoticons or the /me command, they are not found as often (3.4%) as the other forms of conveying emotion. The advantage of the actions portrayed between asterisks is that they can be inserted into a message which otherwise does not convey the performance of an action where as the /me command requires that the whole message be devoted to the communication of an action. The most common use, however, remains as some form of hug that is sent to another user in greeting.

The last category of socioemotional cues examined in this study are paralinguistic. These cues took two forms: vocalized pauses and utterances, as well as vocal emphasis. These two forms really could have been divided into two separate subcategories under paralinguistic cues and tabulated separately. The first form usually appeared to suggest that the user was thinking about a response. As a result, it was not unusual to find hmm, um, and er typed into the dialogue, along with hahaha or hehehe to express laughter. Thus, using these vocalizations in a typed form helped make the CMC dialogue more similar to actual face-to-face transactions. Awws, uh-huhs, ho hums, naaahs, and shhhs also made it into the conversation. Huh or the use of multiple question marks seemed to indicate that the user did not understand something and was asking for clarification much as one would do face-to-face. Emphasis to messages was also added by using multiple exclamation points. This occurred most frequently in greeting friends who had just joined the channel. Capitalizing words was used to intensify the emotional impact of a word, and extra vowels in a word indicated the drawn out inflection that would be used if actually saying the word in that specific response. All of these vocal variations comprised 12% of all messages in the sample studied. Finding paralinguistic cues in greater frequency than other forms of socioemotional cues is not surprising because verbalized pauses, laughter, and vocal emphasis are a common part of face-to-face interaction. Although vocal variations account for more than 12% of relational message exchange in face-to-face interaction, the occurrence of paralinguistic cues shows that people are finding ways to convey these cues in typed dialogue, too.

The individual occurrence of socioemotional cues, however, is of little importance unless the cues can be brought together within an interaction to create shared meaning among the interactants. The following excerpt is a good representation of how various forms of the socioemotional cues examined in this study (with the exception of the /me command) were incorporated into one social interaction. In addition to being a good example of dialogue on IRC, this excerpt exposes a typographical mistake which turned into fun for other users. Since IRC is completely text-based, word games such as this tend to occur. There may not be such a thing as a literal Freudian slip in CMC, but there are typographical errors that can lead to teasing from other users if the mistake can in any way be misconstrued. One such mistake turned into teasing occurred on channel lonely:

```
<user1> well <user> I didn't learn to drive until 1910
<user1> err ooops 1990
<user2> Hehe..
<user3> hehe
<user3> 1910???
<user4> hahaha..., been lying about your age??
<user3> <user1> is soooooooo OLD
<user3> hehe
<user2> She's been lying about her age.
<user1> hahaha D =]
<user1> it was an error
<user2> Sure <user1>, I believe ya.
```

If CMC were devoid of socioemotional cues, this interaction could not have occurred because the conveyance of humor would be impossible. To understand humor, there must be shared meaning. Thus, IRC users have developed verbal and textual cues which substitute for, but are different from, the shared networks of meaning that occur in face-to-face interaction. Without the textual cues, CMC would be impersonal, but through the use of textual cues as messengers of context cues, humor and personal reactions are able to enter into the computer-mediated dialogue.

CONCLUSION

Even though the socioemotional cues occurred in varying amounts from text to text, the fact that they were present in all of the interactions is of importance. Because these cues served as initiated actions or as reactions to other messages, relational information was able to be conveyed through a completely text-based environment. As Reid puts it, "The IRC community shares a concern for care in nuances of language and symbolism, a realization of the power of language and the importance of social context cues..." (1991 no pag). Thus, those participating in interactions in the synchronous CMC environment of IRC have overcome the impersonal factors of reading an electronically encoded message on a computer screen to create a relational community.

The mere occurrence of a CMC "community" indicates that CMC cannot be truly impersonal. Even with the techniques employed by IRC users, the narrow bandwidth or limited channels of communication in CMC is unable to convey the same amount of relational information as quickly as face-to-face interaction. In addition, these conventions can only convey the information of which the sender is personally aware, since the user is sending a message about a cognitive response. Typographical errors can sometimes be equated to the leakage of information which results from nonverbal signals in face-to-face communication. Some of these differences prevent CMC from being able to convey the same information as face-to-face interactions; however, expecting CMC or any form of communication technology to be equivalent to face-to-face communication seems to follow an irrational line of thought.

This particular study has tried to show that CMC is not necessarily an impersonal form of communication, but is actually an environment in which a social community has thrived for over six years. Because IRC creators and users recognized the need for social context cues, the program incorporates methods of portraying those cues into the vocabulary of IRC users. Thus, IRC helps to show that "the physical environment of IRC may be only virtual, but the emotional aspect is actual" (Reid, 1991 no pag). Reid speaks only of IRC but the implication is that the emotional aspect could be realized within the entire community of CMC users.

You Eat What You Are:
An Investigation Of Key Environmental Variables On Food Choice

Laurel Y. Shanaman

Department of Communications
Cedar Crest College
100 College Drive
Allentown, PA 18104

Faculty Advisor:

Dr. James Brancato

Why do people eat what they do? Do we have inborn tastes or are they developed through our socialization process and environmental factors? It is hypothesized that eating behaviors and related food choices are significantly influenced by external factors such as the mass media and peer groups, and that like other learned behaviors, they are difficult to change. This study uses qualitative research techniques to evaluate the relative strength of several key environmental variables on food choices for young women, including different advertising and communication venues and television programming and their related effects on reference group impact.

BACKGROUND

The National Center for Health Statistics (1997), reports that "Thirty-five percent of women and thirty-one percent of men are obese in the United States." The connection between food, nutrition and the media has been demonstrated repeatedly. If people know that media images can lead to over eating or eating "unhealthy foods" then why do people continue to make "bad" food choices? Numerous studies (Sanders, 1995, Martorell, 1996, and Iszler, 1995) have concluded that "food is necessary to sustain life and health." People eat certain foods for a variety of reasons, least which is "good health and nutrition," The concern for good health and nutrition arises from an expanding food environment from which people have to choose. This food environment is often influenced by factors such as politics, poverty, limited personal control, and choice. Food habits are intimately related to our way of life through: values, beliefs, and life situations. Food beliefs may even be generated from misinformation and "fads" rather than sound nutritional knowledge. A person's food habits develop from the environment in which they exist (Williams, 1992).

Food habits are human behaviors which develop from personal, cultural, social, economic, and psychological influences. Habits form through a gradual process of conscious and unconscious learning in which behaviors are reinforced or punished. Culture is a key contributor to the development of food habits through everyday living and family relationships. People learn related behaviors, such as, preparing and serving food and eating rituals, as they mature. A person's behaviors, beliefs and thus culture is also influenced by the media in the form of parent influence or television programming. Images the media portrays have an unconscious effect on the exhibition of food related behaviors (Williams 1992).

In the media there are diverse images of women. The image of beauty is presented as a societal standard. The media has socialized women to believe that their bodies must fit a certain image. As a result, "more than half of all eighth graders in the United States have been on a diet." It appears that society needs to become aware that people's perceptions of diet and nutrition do not always match reality (Editor's Note: Representations of Women in the Media 1997).

According to the Editor's Note: Representations of Women in the Media (1997), different areas of advertising portray women differently. The following examples show the image of women as being tarnished and weakened. In female oriented publications, ads tend to be for beauty products and cleaning products. Women are used to create an image of beauty, attractiveness and elegance so that potential consumers equate these attributes with product usage. Television advertising portrays women as sex objects. Depending upon the target audience, women promote cologne or other 'men's' products, or cleaning supplies for women. Television advertising presents women in a shallow context with goals and inspirations rarely reaching beyond a 'spic n span' clean house or having the hair of "their" dreams. These sort of messages are being sent out to women and men world wide. Women are expected to weigh nothing and to be beautiful (Editor's Note: Representations of Women in the Media 1997).

METHODOLOGY

A qualitative research project was conducted in an attempt to create an objective study on nutritional attitudes and behaviors as influenced by external sources. Research was conducted using four focus groups of young women ages 17 to 22 from a Northeastern women's college. Participants were screened and recruited approximately 1 week prior to the date of the focus groups and mailed a confirmation letter. Telephone confirmation was made one day prior to the scheduled session. A total of 10 to 12 participants were present at each session.

One-hour structured focus group discussions were conducted with freshmen, sophomores, juniors, and seniors. Each session was consisted of two broad sections. In section I, participants discussed their general feelings about nutrition attitudes and behaviors. During section II, family, peer, and media influences were addressed. Focus groups scripts were originally developed and reflected the direct interest of the Northeastern college, a corporate partner, and larger social issues.

KEY FINDINGS

The overall attitudes of participants toward nutrition were neutral. Participants tended to be indecisive when answering questions about nutrition due to confusion over nutritional facts and media messages. For example, they viewed products as unhealthy and then an image portrays healthiness in spite of eating unhealthy products. Participants appeared to experience problems with consistency in their answering patterns when expressing feelings about nutrition and external influences.

Participants expressed negativity toward the media's portrayal of nutrition, health, and image. Participants concluded that the media over emphasizes words, such as "diet" and "thin", to convey messages. Participants felt the media is insensitive toward issues of diversity and generalizes when deciding upon the message conveyed by words and images.

One interesting finding which was consistent across all groups, was the low level of consistency between participant attitudes toward food, health, nutrition and their food related behaviors. Based upon participant comments on the mixed messages received from advertisements, this inconsistency can partially reconciled. Participants tended to feel the media portrayed contradictory images of women on television. For example, the participants saw a thin model eating a bag of chips, this apparent oxymoron may not fool the participants on a cognitive level, they may use these images to ease their conscience as they indulge on foods that are fattening and unhealthy. Thus for many of the participants, they did not think the "bad" food choice would negatively impact their self-image.

Participants noted that healthy and "normal" looking individuals are not seen on commercials. Participants mentioned the Boston Market® commercial as an effective way to show society that consuming food is natural. Participants felt the commercial was able to portray the message that people should be hungry and eat and it is not taboo. On the other hand, while promoting Participants did not feel that the media motivates people to eat healthier or look a certain way. The media tends to cause people to become self-conscious, while showing food commercials to induce hunger.

One positive aspect of nutrition in the media was the amount of nutritional education available to society. Participants felt the media causes society to think about nutrition and health related information frequently and with concern because of commercials on heart disease and health related problems. While being concerned with media images and nutritional information, participants did not view weight as an issue in the nutritional spectrum. Participants were not concerned with media images of weight enough to mimic

BEST COPY AVAILABLE

the idealized images on television. They felt the media was not personally attacking them and therefore, did not see the media as having a strong case against being weight related issues.

It is evident that our socialization shapes many aspects of our life. The influences of family and peer groups are noticeable in the way in which society lives and considers everyday issues. The media definitely has an affect on the attitudes of the participants both negatively and positively. The impact of a family or peer group is even stronger, the family or peer groups are able to change the food choice of the participants through words or actions. It has been hypothesized that media has a large influence on the way people feel about nutrition, it has been noted that family and peer groups ultimately have more influence on individuals than the media. The family has a great deal of control over what the participants consume when in their company. Through, this control the family is able to influence the participants food choices. In actuality the participant will eat whatever they are served. Through this forced food consumption the family was able to influence the participants to look and think about food in a different manner. Participants negatively noted, that families and peers do not generally care about the food they consume, but are concerned with nutrition and image. One's family ultimately sends mixed messages in conjunction with the media. These messages perpetuate feelings of unhappiness and discontentment in one's life. The affect the family unit has on the participants is one of actual food choice.

CONCLUSION

The most interesting aspect of the research was the revelation that yes, participants were influenced greatly by the media in terms of eating habits and media images. They identified with wanting to be thin, beautiful and healthy, however, the motivation to change eating behaviors and attitudes was not significant. It seemed that this attitude is not unnatural in today's society. Images of beauty and health are portrayed and longed for by society. People want to look like those on television, but the reality is that they will never live the life nor have the prosperity of these images. It seems that this realization alone discourages society as a whole from pursuing better overall lifestyles. In this research it was evident that participants had problems with images portrayed as well as, nutrition in general. They did not feel there was any way to change the attitudes of society or the images of the media to reduce conflicting messages.

It is necessary to look at the media in an objective manner when dealing with nutritional images. From a health and nutrition perspective, certain recurring patterns, such as idealizing conformity to images, may prove to be interesting. This conformity seems to be a result of status quo. The exaggeration of an 'ideal' body shape seems to imply a necessity to attain a certain form in order to be fashionable, sexy, attractive, and successful. Conscious and unconscious acceptance of these images is a large factor in the lack of motivation to change eating attitudes and behaviors. These images are so overwhelming to society that it seems like an impossible obstacle to even resemble the images on television. This is an unfortunate reality when looking at ways to improve behaviors and attitudes of society with nutrition and food. As long as these media images continue to plague society negatively, whether that be with an obsessive need to be thin or an impossible image to attain, society will not be able to change the way nutrition and health is viewed. Appealing images seen on television are contrasted by society becoming dependent on quick fixes and products.

Family and peer groups influenced the participants more heavily than the media. Personal contact with family members and peers tended to have a greater effect on participants behavior than the media. Participants felt pressured and influenced by family and peers because of their words and actions. Family members were hypocritical and inconsistent in their own nutritional and eating behaviors by example. Families were critical due to self-interests and social status. Participants were bombarded with contradictory images both on television and from family and peers. Participants were socialized to have it all. The messages that were being sent were those of remaining thin without self-discipline. This caused distress for many young women, the pressure they were receiving from their family and peer groups was tremendous. Family, peer and media influences present real choices to society that distract people from making a choice for their own well-being. Let society not become so consumed with other agendas that they forget who is the ultimate decision maker, themselves.

LIMITATIONS AND FUTURE RESEARCH

Given the qualitative nature of this research, there are limitations in terms of generalizability and external validity. The use of a convenience sample and small sample size are both a external validity and generalizability issues.

Currently further research is being conducted on a quantitative level. One issue being investigated is the perception of skinny versus healthy. In further research it will be beneficial to expand on the pilot study by using a co-educational institutions and male population for comparison. The use of a male population will enable the exploration of varying perspectives on nutrition and external influences. Media images should be further investigated. Questions need to focus on the specifics of advertisements and television programming. Consumer attitudes towards product promotion can be explored through the use of product samples or direct marketing techniques. Future research should explore why consumers are discouraged by images in the media and thus, would prefer to make less externally influenced nutritional decisions. A more in depth investigation into external factors, such as, the effect of media images on individual thoughts, feelings, motivations and attitudes regarding nutrition.

The Nurse-Patient Continuum
A Nursing Model

BACKGROUND

An inductive research process in which case analysis was used to identify phenomena concerning nursing practice was adopted. Each member of the group analyzed three separate and personal clinical cases in which relevant phenomena were identified. Then the phenomena were grouped into concepts and the relationships between the concepts were articulated. Each member identified the commonalties between each of the three cases and discussed patterns that were derived. This process was then conducted in a group setting in which common concepts were identified amongst fifteen different clinical cases (Boak, Dickerson, Jackson, Fabiani, & O'Quinn, 1996). Based on the relationships between the concepts a conceptual model was developed.

The utilization of the inductive research process allowed the development of a conceptual model which could be used to help guide and direct nursing practice, as well as identify theoretical propositions that could be tested. In this paper, the model will be described followed by a discussion of theoretical propositions that have been specified from the nurse-patient continuum model.

NURSE-PATIENT CONTINUUM

The Nurse-patient Continuum was developed by a group of baccalaureate nursing students who designed a model which coincides with Peplau's theory of therapeutic relationships that occur between the nurse and the patient (Forchuk, 1994). The model demonstrates a cyclic process consisting of four wheels being turned by links in a chain (see figure 1). The wheels were labeled as individual constructs: nurse perceptions, nursing care, patient outcomes, and nurse outcomes. Within each construct (wheel) five concepts (links in the chain) were identified: nurse perceptions-spirituality, health status, mental well-being, support systems, and culture; nursing care-support, empathy, therapeutic touch, communication, and compassion; patient outcomes-acceptance, hope, trust, support, and well-being; nurse outcomes-confidence, sense of purpose, growth, competency, and holistic outlook.

The nurse-patient continuum provides a framework for holistic centered nursing care. The nurse's perceptions have a direct impact on the care that is delivered. When these perceptions are positive and holistic-centered, nursing care will eventually empower the patient (Fosbider, 1994). As the patient becomes more empowered this too will impact greatly on the nurse's experience. The result being that growth on the part of the nurse influences the care that will be given to future patients (Bailie, 1996). It is important to note that the continuum can only exist and flow when all the positive components (links) are involved.

Although this may seem extremely simplistic, it is the view of the authors that this is the most forgotten part of nursing care. As healthcare continues to be dominated by politics, insurance companies, and financial issues nurses cannot forget their primary reason for being in healthcare, the patient. Nurses must initially concentrate on their perceptions of the patients for this is what sets the continuum in motion. The more effective the care delivered is the better the patient outcomes will be. The more positive outcomes that are generated on behalf of the patient, the greater the chance that the nurse will experience positive outcomes (Astedt-Kurki, and Haggman-Latide, 1992). As the nurse continues to care for patients, they will learn that each interaction with their patients is an opportunity for growth as well as an increase in their competency, confidence, sense of purpose, and view of holistic health. These implications are crucial to quality care and the advancement of the nursing profession (Styles, 1991).

THEORETICAL PROPOSITIONS

The nurse-patient continuum is not only able to be used as a basis for clinical practice but, also allows for the specification of relevant theoretical propositions which can be studied. It is important that issues relevant to nursing's clinical practice be tested. The following theoretical propositions have been identified:

(1) There is a positive relationship between a holistic nurse perception-spirituality, health status, mental well-being, support systems, culture and improved nursing care delivered.

(2) There is a positive relationship between nursing care and patient hope, trust, and support.

(3) There is a positive relationship between patient outcomes such as acceptance and nursing outcomes which include growth and holistic outlook.

CONCLUSION

Through the inductive research process individual case studies were analyzed. Concepts were identified and relationships were articulated. Based on these relationships a conceptual model was developed and theoretical propositions were specified. Through this process, issues relevant to and requiring greater understanding in clinical practice were identified and can now be studied.

Assessing the Effects of HIV/AIDS Peer Education on High School and College Freshmen

Cara Catalino, Erin Clune, Megan Gordon, and Marie Neilan

Department of Nursing
University of Scranton
Scranton, Pennsylvania 18510

Faculty Mentors:

Patricia A. Bailey and Dona Rinaldi Carpenter

Despite all the information available today to high school and college students, the number of HIV cases is growing at a deadly rate. The prupose of this study is to determine whether certified American Red Cross HIV/AIDS peer educators are effective in teaching high school and college freshmen about HIV prevention. The Health Belief Model, which focuses on knowledge, attitude, and behavior, provides the framework for the study. An experimentor developed tool of 20 "yes" and "no" questions was developed regarding transmitssion, myths, prevention, and testing. The tool was distributed as a pre-test and a post-test to 67 high school freshmen and 86 college freshmen. Data was analyzed according to the specific categories of the questions. Precentages of correct answers were determined for both groups for each question. Overall, there was an increase in knowledge; however, some minor limitations were noted which could be addressed with later research studies.

INTRODUCTION

Since 1981, society has been facing the epidemic of AIDS. AIDS affects all nations, ethnicities, races, sexes, and ages. According to the Centers for Disease Control and Prevention (1995), the number of reported AIDS cases in the United States by the end of 1995 was 319,849. The key to stopping the spread of HIV/AIDS is to know the essential facts regarding transmission. Integration of essential attitudes, behaviors, decision making and a personal belief system is critical. HIV/AIDS education is becoming more prevalent, as many schools have incorporated HIV/AIDS education into the curriculum as a required class; and in others it has become an elective. The Red Cross is responsible for the creation of peer education regarding HIV/AIDS. Many young people have taken the initiative to become certified to teach HIV/AIDS education in elementary schools and high schools, as well as colleges. The hope for this type of education is that individuals of the same age will be more attentive to the information being presented by their peers.

THEORETICAL FRAMEWORK

The Health-Belief model is a perspective that is based on the relationship between a person's beliefs and actions. Four main factors influence that relationship: age and developmental state, previous experience with illness and health, personal thoughts and goals in relation to health and illness, and the sociocultural influences (Craven and Himle, 1992, 174-175).

This model relates extremely well to this study. HIV/AIDS is almost 100% preventable, but is an epidemic in our country. Knowledge and awareness are what will change actions and behaviors. Knowledge is key in HIV prevention and this model is structured on health and beliefs about one's health. "The health belief model provides insight into the connection between the way a person sees his or her response to health, illness and treatment (Craven and Hirlne, 1992, 174-175)."

EXPERIMENTAL DESIGN

The focus of this research project was to see the effects of HIV peer education using a sample of approximately 80 freshmen high school students and 80 college freshmen as subjects in this quantitative, descriptive study. The data collectors are certified HIV peer educators who have conducted peer education classes in a private high school, as well as several freshmen dorms at a private college. The surveyed students have been educated for approximately 45 minutes on HIV/AIDS transmission.

The peer educators facilitated a game called "the transmission game," which consists of students actively participating in the HIV/AIDS presentation. The game breaks down HIV transmission into three groups which are "no risk," "high risk," and "needs more information." There are a number of cards given out with particular situations, such as "getting bit by a mosquito" and "donating blood." The students then take their card and place it under the appropriate category. Once the cards are situated on the board there is a discussion between the facilitators and the students in relation to HIV. Throughout the presentation, the facts of HIV transmission are discussed and the students are able to ask questions to further their knowledge of HIV/AIDS.

The tool that has been developed is a pre-test and a post-test that consist of 20 questions pertaining to knowledge of HIV/AIDS. The students replied to each question by circling "yes" or "no." The same tool was used for both the pre-test and the post-test. The pre-test was distributed to the students prior to the week before the peer education class by their respective health education teacher and dormitory resident assistant. The post-test was distributed approximately one week following the peer education class and collected by their respective health education teacher and dormitory resident assistant. .

DATA ANALYSIS

Data from both pre-tests and post-tests was collected by the researchers and grouped according to the number of "no's" and "yes's" for each question. High school freshmen and college freshmen questionnaire results were analyzed separately. There were a total of 67 pre-tests and post-tests from high school; and a total of 86 pre-test and 69 post-test from college students.

RESULTS

Table 1: Increase in Correct Post-test Answers on Prevention

Questions Regarding:	High School	College
Type of condom	25%	3%
Birth control pill	0%	3%

Table 2: Increase in Correct Post-test Answers on Myths

Questions Regarding:	High School	College
HIV in heterosexual women	43%	12%
HIV in homosexuals	45%	17%
Identifying an HIV+ person	1%	0%
Casual Contact	2%	5%
Insect transmission	5%	0%
Cure for AIDS	0%	7%
"Man's Disease"	3%	0%
"Innocent Victims"	6%	0%

Table 3: Increase in Correct Post-test Answers on Transmission

Questions Regarding:	High School	College
Sharing needles	0%	1%
Influence of Drugs and Alcohol	29%	32%
Mother to child	0%	1%
STD's	12%	22%
Blood donation	31%	14%
Blood transfusion	0%	0%

Table 4: Increase in Correct Post-test Answers on Testing

Questions Regarding:	High School	College
Testing at Public Health Department	17%	1%
Anonymous Testing	0%	2%
False Negative Test	3%	0%
Detection of virus strains	13%	16%

CONCLUSION

By examining the data analysis, it can be suggested that HIV/AIDS peer education is effective in increasing students' knowledge of HIV and AIDS. The research suggested the most significant improvements after education were in the following areas: prevention issues; myths on homosexuality; use of drugs and alcohol; blood donations; and testing (Mulvihill, 1996). High school freshmen's knowledge had a greater increase compared to college freshmen's knowledge after peer education. From analyzing the data, it is suggested taht college freshmen had a higher level of HIV/AIDS knowledge before peer education was initiated. This information is consistent with the literature regarding HIV/AIDS knowledge of a college level student (Calamidas, 1991).

The most significant change after education was the destruction of the myth that only homosexuals have a significant risk of contracting the virus. This can be supported with the high increase in post-test responses. In the past, some research studies suggested certain myths were evident in high school and college students (Holzman, Anderson, Kann, Arday, Truman & Kolbe, 1991). However, the myths studied in this research project implied that the majority of these myths were no longer presumptions in this population. Overall, the findings suggest that HIV/AIDS Peer Education is effective in teaching high school and college freshmen.

Relationships of Self-Perception of Balance, Technological Measures of Balance, and Fall Events Among Individuals with Parkinson's Disease

Katiya L. Leal

Department of Adult Health
Indiana University School of Nursing
1111 Middle Drive
Indianapolis, IN 46202-5107

Faculty Advisor

Nancy E. Dayhoff, Ed.D., RN

Individuals with Parkinson's disease (PD) experience balance problems that may result in falls. One factor that may contribute to falls is incongruencies between a person's self-perception of balance and actual postural stability. If incongruencies exist, appropriate strategies may not be implemented to decrease the risk for falls. Instruments to measure self-perception of balance are not reported in the literature. The purposes of this study were to evaluate 1) reliability and 2) criterion-related validity of a new instrument to measure perceived balance by examining relationships between: (a) responses to 10 items measuring self-perception of balance with percent of stability on 10 measurement conditions assessed by a posturography instrument, and (b) self-perception of balance and the number of fall events. A convenience sample of 15 subjects was obtained from an ongoing multidisciplinary study. Data were collected by two instruments: a 10-item Self-Perception of Balance Questionnaire (SPBQ) and a computerized posturography instrument, Smart Balance Master® (SBM®). Findings suggest that the SPBQ demonstrated evidence of reliability for the six items measuring automatic control of balance (alpha= .93) and the four items measuring voluntary control of balance (alpha= .89). Evidence of validity of the SPBQ was demonstrated for automatic control of balance ($r= .70$, $p< .004$). Relationships among the SPBQ's voluntary movement items and the SBM®'s conditions were non-significant ($r= -.11$, $p< .70$). Relationships between number of fall events and SPBQ scores were non-significant for automatic ($r= -.39$, $p< .24$) and voluntary ($r= -.23$, $p< .50$) control of balance.

BACKGROUND

Parkinson's disease (PD) is a slow, progressive, degenerative central nervous system (CNS) disorder characterized by four classic features: slowness and poverty of movement (bradykinesia); muscular rigidity; resting tremor; and postural instability (Berkow & Fletcher, 1992). It is estimated that PD affects 1 to 1.5 million Americans and is a leading cause of disability (Lombardo, 1992). Approximately 1 in 50 persons, aged 60 years and older, develop PD (Field, 1991). Duvoisen (1991) states that PD is expected to increase as our aged population increases. PD is not a life-threatening disease; it is life-altering due to its chronic progressive nature. Life-altering responses may result from an individual's self-perception of his/her health.

Persons experiencing PD may alter their lifestyle in one or more areas, such as functional activity. The alterations may occur due to perceived balance impairments, which may lead one to feel threatened about falling. Falls are costly and estimated to add seven billion dollars to the U.S. health care expenditures annually (Miller, 1995). One of the factors which may contribute to falls is the incongruency of balance perception with sensitive technological measure of stability. It is important to investigate self-perception of balance among this population because they are at a high risk for falls (Tinetti & Speechley, 1989) and their perceptions of balance may predict life-alterations and fall outcomes (Lipsitz, Jonsson, Kelley, & Koestner, 1991).

Instruments to measure self-perception of balance are not reported in the literature. Technological instruments are available to assess dimensions of balance, they are expensive and not portable, limiting their use with patients. If a questionnaire were developed with evidence of reliability and validity, it could be incorporated into patient assessments by nurses and other health care providers. Patients identified with possible balance problems through this screening could be educated regarding fall risk and preventive strategies in an effort to decrease falls. Also, these patients could be referred to balance laboratories for thorough evaluation.

The purposes of this study were to evaluate 1) the reliability and 2) criterion-related validity of a new instrument to measure perceived balance by examining relationships between (a) responses to 10 items measuring self-perception of balance with percent of stability on 10 measurement conditions assessed by a posturography instrument, and (b) self-perception of balance and the number of fall events.

THEORETICAL/CONCEPTUAL FRAMEWORK

According to the Systems theory, balance is a complex process and involves coordinated actions of biomechanical, sensory, motor, and central nervous system components (Nashner, 1994). Biomechanical is defined as "the position of the body center of gravity relative to the base of support." Sensory is defined as visual, vestibular, and somatosensory inputs. Motor is defined as the complex system of joints and muscles involved. CNS components are the adaptive processes necessary to modify the sensory and motor components, including automatic and voluntary control of balance (Nashner, 1994). Individuals with PD may experience dysfunction in one or more of these areas resulting in balance impairments which potentially can lead to falls.

When balance dysfunction occurs, an individual may appraise himself as ill (functional ability below perceived capability level and an uncomfortable sense of self) (Lyon, 1996) and alter his functioning according to the degree of threat perceived. Appraisals, include self-perceptions, and are evaluated as threatening and non-threatening. Coping with threats may lead to decreased functioning or fall prevention, while appraisals of non-threatening characteristics may lead to maintenance of normal functioning or failure to take appropriate protective measures. Appropriate appraisals and coping behaviors must occur for optimal functioning and prevention of falls. Therefore, reliable and valid balance assessment instruments are needed for appropriate diagnosis and treatment of balance impairments.

METHODOLOGY

Sample

A convenience sample of 15 subjects was obtained from individuals with PD who were participating an existing multidisciplinary study of the effects of pallidotomy surgery in individuals with PD at Indiana University Medical Center. Nine subjects were male and 6 were female with ages ranging from 49 to 78 years (mean = 64.93). All subjects had been diagnosed with PD for at least three years. The subjects were evaluated for inclusion criteria prior to participation. Eligible subjects exhibited: 1) intact cognition demonstrated by following a two-part command, such as raising a hand over their head and holding it there; 2) vision of standard newspaper print, as stated in a self-report, and 3) the ability to stand unassisted for five minutes.

Instruments

Self perception of balance was measured by participants answering a 10-item questionnaire which was developed to simulate the measures of the SBM* on automatic control of balance (Eyes Open, Eyes Closed, Sway Vision, Eyes Open/Sway Surface, Eyes Closed/Sway Surface, Sway Vision/Sway Surface) and voluntary control of balance (Limits of Stability) (See Table 1). Items 1, 2, 7, 8, 9, and 10 evaluated automatic control, while items 3, 4, 5, and 6 evaluated voluntary control. Two examples are as follows: 1) Question 8 (automatic): "You are on an airplane and need to walk to the restroom. You stand on the floor without holding on to anything. As you are walking the airplane experiences slight turbulence and the floor seems to be moving slightly under your feet. How steady is your balance?"; 2) Question 6 (voluntary): "You are standing alone in your home in the daylight. You are putting on your coat to go outside to get the mail. You have one arm in your coat and now must reach behind yourself with the other arm to insert it into the coat sleeve. How steady is your balance?". Individuals selected perceived stability on a Likert scale with responses ranging from (1) Very Unstable-"I know I will fall" to (5)Very Stable-"I know I will not fall". To allow for possible instances in which and individual could not evaluate his/her balance in the situational question an N/R (No Response) option was added, valuing 0. A summative score was obtained for the self-perception of balance score. The possible scores ranged from 0 (No Response) to 50 (Very Stable).

Table 1. SPBQ item correlation with SBM® condition. [1]Automatic control of balance. [2] Voluntary control of balance.

SPBQ ITEM	SBM® Condition
Question #1	Eyes Open (EO)[1]
Question #2	Eyes Closed (EC)[1]
Question #3	Front Limit of Stability (FLOS)[2]
Question #4	Right Limit of Stability (RLOS)[2]
Question #5	Left Limit of Stability (LLOS)[2]
Question #6	Back Limit of Stability (BLOS)[2]
Question #7	Sway Vision (SV)[1]
Question #8	Eyes Open/Sway Surface (EO/SS)[1]
Question #9	Eyes Closed/Sway Surface (EC/SS)[1]
Question #10	Sway Vision/Sway Surface (SV/SS)[1]

Fall events were measured by self-reports of subjects, obtained through a guided interview and recorded on the Fall Inventory (FI). The FI consisted of questions which were easily answered and captured the dimensions of fall events regarding their complexity and relationship to postural instability (Dayhoff, Mullennax, Leal, & Hall, 1996).

Objective balance was measured by the SBM®. The SBM® is a dynamic posturography instrument which is a software driven computerized instrument consisting of dual forceplates that rest on pressure transducers and measure automatic and voluntary control of balance (NeuroCom, 1993). The SBM® demonstrated reliability (alpha = .73 - .85) in a previous study involving an elderly population (Wigglesworth, Dayhoff, & Suhrheinrich, 1995).

Procedure

An explanation of the study was provided and informed consent was obtained. Self-perception of balance was evaluated prior to the SBM® testing. A 10-item questionnaire was utilized as the evaluation tool. Objective measures of balance were then obtained using the SBM®. Complete testing time varied, ranging from 1 to 3 hours, depending on client needs.

FINDINGS

Findings suggest that the SPBQ demonstrated evidence of reliability for the six items measuring automatic control of balance (alpha= .93) and the four items measuring voluntary control of balance (alpha= .89). Evidence of validity of the SPBQ was demonstrated for automatic control of balance. The mean of the automatic SPBQ score was significantly correlated with the average automatic SBM® score ($r = .70$, $p < .004$). The relationship between the SPBQ's average score on the voluntary movement items and the average SBM®'s voluntary conditions was non-significant ($r = -.11$, $p < .70$). Graphical analysis demonstrated that self-perception of balance scores were congruent with the SBM® score (See Figure 1). Relationships between number of fall events and SPBQ scores were non-significant for automatic ($r = -.39$, $p < .24$) and voluntary ($r = -.23$, $p < .50$) control of balance. Graphic analysis depicted the variability between the self-perception of balance score and the number of fall events that individuals stated they experienced (See Figure 2).

CONCLUSION/RECOMMENDATIONS

The SPBQ was internally consistent for items measuring automatic and voluntary control of balance. There is evidence that the SPBQ is a valid instrument for measuring automatic control of balance in individuals experiencing this type of balance impairment.

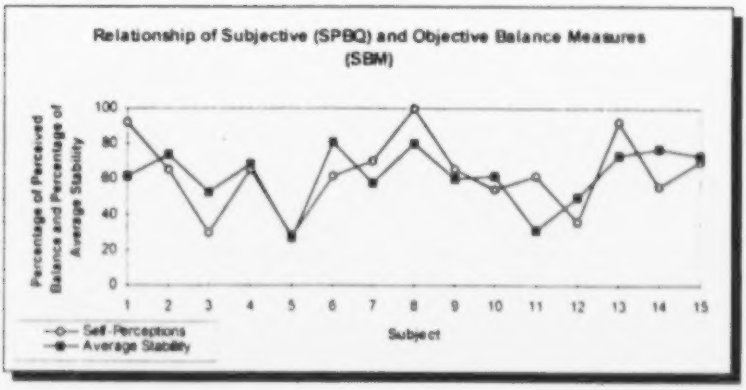

Figure 1 Relationship between SPBQ percentage score and SBM* average stability score according to each individual subject

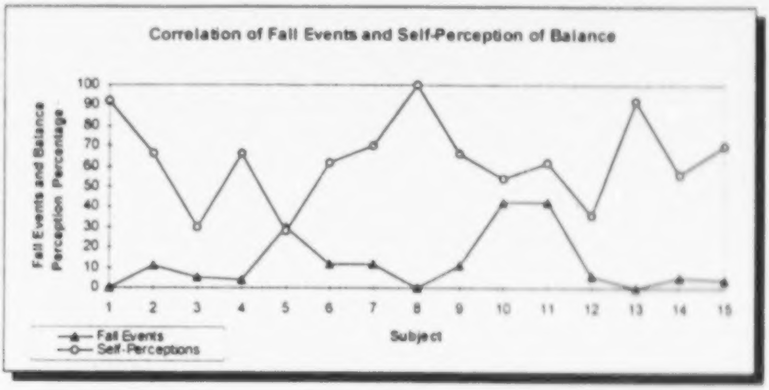

Figure 2: Correlation of number of fall events as self-reported by individual subject and the SPBQ score

Evidence of validity was not supported when assessing correlations of fall events with self-perception of balance. This finding may reflect the likelihood that some non-fallers with poor perception of balance may have taken protective measures to prevent falls, while some individuals with poor balance may have chosen to maintain their activity inspite of their perception of balance (N Dayhoff, personal communication, April 21, 1997).

It is recommended that the SPBQ be considered as a possible instrument in assessing persons with balance impairments involving automatic control in the clinical setting. It is suggested that further testing be conducted on a larger sample size. The items measuring voluntary control of balance need to be modified and re-tested before consideration for clinical practice. Future research needs to include use of protective measures to prevent falls as a covariate in understanding relationships between self-perception of balance and number of fall events.

Depression: Prevalence, Causes, Manifestations, and Repercussions Associated with Elderly Disability

Nicole Lovell

Faculty Advisor: Clyde B. Killian, Ph.D.

The average life span of individuals in the United States has increased as a result of contemporary science providing refined health care. Consequently, health care professionals have witnessed an expansion in the number of elderly in patient demographics. Due to the interweaving of physical and mental problems, depression often accompanies aging individuals encountering physical impairments, functional limitations, and disability.

How prevalent is depression in the elderly, and why are the elderly particularly vulnerable to developing it? How can depression be recognized among the geriatric population, and how is it correlated to physical disability? And lastly, what are some ways to prevent depression from manifesting itself into the lives of those who are elderly, including those facing disability? A discussion of the prevalence and causes of depression associated with elderly illness, how depression manifests itself in the lives of functionally disabled elderly individuals, and the repercussions depression may have on the individual and his or her caregiver, follows.

Although some sources state the percentages to be as high as sixty-five percent, the National Institute of Aging declares that fifteen percent of people over the age of sixty-five experience depression.[1,2] It is considered to be the most common emotional problem that the elderly experience, providing for them the highest suicide rates across any age group.[3,4]

Despite these numbers, eighty percent of older adults with depressive symptoms receive no treatment at all.[4] Less than nine percent of clinically depressed elderly individuals in a hospital setting were actually diagnosed by their primary physicians as depressed.[5] This may be because of the preconceived connotations our society holds about aging which delays opportunities for clinically depressed elderly individuals to obtain treatment. The cognitive changes that accompanies depression, such as difficulty thinking clearly or concentrating, is often misdiagnosed as dementia in elderly patients on a clinical level and senility on a societal level, or, as one might say, "a natural consequence of growing older". Also during exams, physicians seem more inclined to focus on physical rather than mental complaints from elderly individuals.

Elderly individuals may also be unable to access information about depression due to expense or unawareness. Low-income elderly may be unable to afford expensive psychotherapy where reduced or deterred fee therapy is not available. Medicare has also demonstrated in the past to be more available for physical care than mental health care. Elderly individuals may also be either too embarrassed to admit or not educated enough to realize they may have characteristics of a person who is clinically depressed.

The elderly are particularly vulnerable to developing depression due to the combination of endogenous and reactive factors. Endogenous factors occur in the absence of clear external events and are biologically based. These factors include genetics and brain disease.[6] Depressive disorders are estimated to occur among ten to thirty percent of Alzheimer's patients, forty to fifty percent of Parkinson's patients, and up to sixty-three percent of stroke patients.[6,7] Other medical illnesses often associated with depression include thyroid disease, occult neoplams, deficiency states, collagen vascular disorders, alcoholism, and infection. Drugs, including antihypertensives, antiparkinsonians, narcotic analgesics, corticosteroids, and certain drug combinations, may also elicit depressive symptoms by affecting the physiology of the brain.[8]

Reactive factors are linked to negative events, and are most likely to reflect psychological, social, and physical environmental factors. Some reactive factors particularly faced by older adults include: loss of significant others, a feeling of not living up to one's potential in the present or the past, loss of self-esteem through the loss of a job or retirement, decreased rates of participation in potentially reinforcing activities, a feeling of a loss of control of important events and outcomes in one's life, and little reinforcement from the environment. Not only are the patients themselves depressed, by thirty percent of elderly spousal caregivers have been shown to develop depression.[2]

The effects of depression can be categorized into four types of deficits: motivational, cognitive, affective, and those demonstrated by motor behavior. Motivational effects include not being able to get out of bed in the morning, reduced level of social participation or interest in pleasurable activities, and failure to respond to praise or rewards. Cognitive changes, which is one of the reasons depression is often misdiagnosed as dementia, include difficulty concentrating or thinking clearly, thinking negatively about oneself and one's future, feeling guilty or remorseful about past misdeeds, and lack of self-esteem. Some affective features include changes in mood, persistent periods of feeling depressed, tearfulness or crying, increased irritability, jumpiness, or loss of temper. Changes in motor behavior include moving about or talking more slowly than usual, changes in sleep habits, changes in appetite and weight, and functioning less effectively than usual at work or in the home.[2]

Depression has been shown through research to significantly affect an elderly individual who is recovering from impairments, functional limitations, or disability. Depression impairs physical activities, language function, resumption of social activities and community service involvement and promotes social isolation, poor motivation, dependency, and loss of control for the post-morbid individual.[6,8]

If depression is left untreated in elderly hospitalized patients, which has been proven to occur in many elderly depressed individuals, consequences include longer hospital stays, failure to achieve and maintain functional gains, intellectual impairments, depressed moods, and decreased community integration.[6]

Prevention of the development of depression can be accomplished through the efforts of the elderly individual themselves, caregivers, and health care providers. Preventative measures include social support, humor, distortion of reality, physical activity, control over day to day events, referral, education, community integration, and the recognition of different cultural perspectives.

Social support and depression have been linked in a study by Siegel and Kuykendall. They found that widowers who have a limited social support network are at a greater risk of developing depression than those who have extensive social support networks, such as those who belong to a church or synagogue. Staying active in the community is one way to develop social support networks.[8]

The greater one's sense of humor is with moderate and high levels of stress, the less chance the individual has to acquire depression. Humor may be one way to discharge built up tension from stress or to distort reality. The distortion of reality, optimistic illusions and biases about the amount of control we have over our lives are psychologically adaptive. It has been proven that judgment and perception of depressed people are not distorted, but actually quite realistic. Emotionally health people are the ones who use distortion to unconsciously protect themselves from the realities of life.[2,10]

Physical activity may also decrease a person's opportunity to develop depression and help as treatment. Various women who were involved in aerobics classes were found to have a significant amount of less stress and depression than those who were not. This could be attributed to the increased control over arousal and the relaxation that often occurs after physical activity.[10]

Control over day to day events was measured in a study with individuals in a nursing home. These individuals were divided into two groups, equal in physical health. One group had considerable control over day to day events and the second group had significantly less control. One and a half years later, the group that had more control experienced less deaths than the group that had decreased control. This may be attributed to learned hopelessness. Learned hopelessness is "a psychological state that results when an individual perceives that events in his or her environment are uncontrollable" and occurs when people learn that desired outcomes are independent of their voluntary behavior. Learned hopelessness results in the person feeling convinced that there is nothing that he or she can do to escape the situation, and the result is emotional listlessness, apathy, and depression.[10]

For health care providers, there is a multitude of screening devices that may be used if depression is suspected in an elderly individual. These scales include the Zung Self-Rating Depression Scale, the Popoff Index of Depression, the Beck Depression Inventory, and the Geriatric Depression Scale.[11] Health care professionals may also take the proper steps, depending on the setting, to refer the depressed patient to their primary physician.

Health care providers also must be able to provide the information regarding the disease process with the patient, family, and caregivers by educating the them on what the patient has experienced, what the patient may potentially experience, and the importance and appropriateness of positive support. They must also be able to formulate strategies in the hospitalized setting to facilitate community reintegration. This would include planning on the health care providers part and depends on the patient's medical, functional, psychological status, and the caregivers commitment to socialization. Home assessment, social support, and resource referral have also been shown to facilitate community reentry.[6]

Not only specific to depressed patients, health care providers must also be able to recognize the difference of cultural perspectives. When a patient and a health care provider have differing cultural ideas about health and illness, the ability to provide care may be greatly reduced. To supplement this, efforts should be made to evaluate the individuals cultural perspective and include the patient's beliefs, values, diet, and customs into the care plan. Culturally reliable educational materials should always be provided for the patient and family to improve understanding and facilitate compliance with the prescribed treatment regimen.[6]

In conclusion, it is important for our society, in particularly those involved in health care profession, to recognize the prevalence, manifestations, and repercussions of depression present with elderly disability because, as physical therapist Ruth Purtillo once wrote, "Emotional health also affects physical health, and all too often this aspect is neglected."

ACKNOWLEDGMENTS

The author wishes to express appreciation to Amy Helling for all of her help.

Medical Costs and Correlates of Gunshot Wounds in Travis County, 1995

BACKGROUND

"The choice today is not between violence and nonviolence. It is either nonviolence or nonexistence," said Martin Luther King, Jr. (1). Ironically, it was a bullet from a gun that ended his life. Within four consecutive years on the school grounds at Thomas Jefferson High School in New York, 70 students were killed, shot, stabbed or permanently injured (1). According to a report prepared for the New York state assembly, 50% of the 1,900 Jefferson High School students have some type of puncture wound on their body on any given day (1). In New Orleans, "preschoolers learned to dive for the floor in 'shooting drills'" (2). A case study of gang members revealed "many saw themselves as soldiers ready to do battle with an adversary...we got to protect our colors" (3).

The preponderance of violence that involves guns has severe consequences for hospital trauma care systems. Many patients of gunshot wounds do not have medical insurance (8-10, 13, 21-27) and trauma care for this type of injury is extremely expensive (8-10, 12-13, 20-27). The secretary and chairman of the legislative committee for the American Trauma Society, Dr. Howard Champion, said, "uncompensated trauma care is the Achilles' heel of the American health care system" (4). Firearm-related injuries continue to be a leading cause of death in the United States (6-19). Injuries attributed to firearms are the eighth leading cause of death in the United States and are the second leading cause of death for Americans aged 10-34 years (14). Among the Western industrialized countries, the United States has the highest rate of firearm-related deaths (13). Researchers at the CDC reported that from 1968 to 1991, firearm-related deaths increased by 60% (from 23,875 to 38,317) in the United States, and it is projected that by the year 2003, the incidence of firearm-related deaths will exceed the incidence of motor-vehicle crashes. Therefore, firearms will become the leading cause of injury-related death, which is the leading killer for persons aged 1-44 years in the United States (16). In Texas, the number of firearm-related deaths had exceeded the number of motor-vehicle-related deaths by the year 1991 (16). Researchers at the CDC also reported that during 1991 the 38,317 deaths caused by firearms were the fourth leading cause of years of potential life lost before age 65 (YPLL-65) in the United States, accounting for 1,072,565 YPLL-65 that year (14). The report explained the leading three causes of YPLL-65 in 1991 were nonfirearm-related unintentional injuries (2,002,616), cancer (1,772,010), and heart disease (1,312,765). However, from 1980-1991, the firearm-related YPLL-65 increased 13.6%, while the YPLL-65 caused by nonfirearm-related unintentional injury and heart disease decreased 25.2% and 18.1%, respectively. The YPLL-65 caused by cancer increased 1.1% during this same period (14).

Although firearm-related injuries are a serious problem in the United States, little is known about the extent and cost of firearm-related injuries in Travis County, Texas. The purpose of this study was to broaden our understanding of the medical and financial burden at our local level with regard to patient demographics and medical costs of gunshot wound patients. This study sought to answer three questions: (1) What was the average demographic profile of gunshot wound patients in Travis County?, (2) What were the costs for treatment of the gunshot wound patients and what proportion of this total is publicly funded or uncompensated?, and (3) What were the influential predictors for the variance in length of stay, costs and discharge condition?

METHODS

Data Collection:

Brackenridge Hospital is a Major (Level II) Trauma Center located in Austin, Texas. The Brackenridge Hospital Trauma Registry was utilized to retrospectively identify hospitalized gunshot wound patients. Patient data were based on: (1) was admitted to the Brackenridge Trauma Department between January 1, 1995 and December 31, 1995, (2) had a gunshot wound diagnosis according to classification in the Registry, (3) was a Travis County resident according to zip code, and (4) was admitted to Brackenridge Hospital. From the list of patients who fulfilled this criteria, data were abstracted related to demographics, medical costs, type of medical insurance, discharge condition, and injury type and severity. No data were available on the type of gun or bullet that caused the injury.

Variables:

Demographics: Patient demographic data included age, gender, and race. Drug use: Admitting physicians' disgression determined who was tested for the presence and amount of alcohol and illegal drugs. Results of laboratory tests were included in the data set. Discharge condition: The discharge condition indicates the patient's level of functioning upon discharge from the hospital, and

BEST COPY AVAILABLE

is based on an ordinal scale from 1 to 5, with 1 being "good, previous level of functioning" and 5 indicating "death". ICD-9: The International Classification of Diseases, ninth revision, (ICD-9), was used to assess and classify the location and severity of the gunshot wounds. For statistical analyses in this study, preexisting subclassifications of the ICD-9 Manual are used.

Medical Insurance: A personal letter from the Brackenridge Hospital Emergency Director provided categories and definitions for types of medical insurance. The patient's medical insurance was classified as Private or Public/Uncompensated. Private, or commercial insurance, is defined as "any patient covered by a 3rd party payor other than a government entitlement program". This includes: Blue Cross, Commercial Insurance, HMO, Preferred Providers, City of Austin Insurance, and Champus. Public funded is defined as "any patient covered by a government entitlement program", and Uncompensated is "any patient not covered by any 3rd party payor who is considered charity care or bad debt, including all patients who may be retroactively eligible for public assistance". Public and Uncompensated includes: Contract, Certicare, MAP, Medicare, Private Pay, Law Program (jail), City/Travis MAP, and Pending MAP. Reimbursement data were not calculated until after June 30, 1996 to allow ample time for reimbursement transactions. Costs: Medical costs only included charges for inpatient care; Physician's fees are not included. Length of Stay: Length of stay (LOS) was based on dates of admission to the hospital and date of discharge from the hospital.

Analysis:

Descriptive statistics were used to describe the patient. Data were examined for outliers and coding errors. All analyses were carried out using SPSS for Windows. Correlations and linear regressions were conducted to identify associations between demographics, discharge condition, costs, length of stay and drug use.

RESULTS

Sample Description: Of the 2,186 trauma admissions between January 1, 1995 and December 31, 1995 at Brackenridge Hospital, there was a total of 138 gunshot wound patients and 111 were Travis County residents. The mean age was 24 years (s.d = 9.96), with a range of 1 to 66 years. Sixty per cent of the patients were between the ages of 15 to 24 years. Of these 111 patients, 87% were males. Thirty-five per cent of the patients were Hispanic, 31% Anglo-American, 30% African-American, 1% Native American, and 4% other. In comparison, in Travis County there were 62% Anglo-Americans, 11% African-Americans, and 24% Hispanics.

Eighty of the patients were tested for blood alcohol levels, and of these, 44 had a measurable blood alcohol determination. Twenty (18%) were legally intoxicated, with a blood alcohol concentration >100 mg/dL. Sixty-one patients were tested for the presence of illegal drugs: 16 (14%) were positive for tetrahydrocannabinol (THC) (100 mg/dL) and 12 (11%) were positive for cocaine.

Costs: The mean length of stay was 4.67 days (s.d = 6), with a range of 1 to 30 days. Total hospital charges for the 111 patients were $1.66 million, of which $1,056,000 (66%) was uncompensated or publicly funded. The average hospital charges were $15,000 per patient (s.d = $19,234), ranging from $963 to $120,000 per patient. See Table 1 for incidence and costs of gunshot wound hospitalizations for each type of ICD-9.

Table 1: Incidence by ICD-9 and Costs of Firearm-related hospitalizations for Travis County residents at Brackenridge Hospital, 1995.

ICD-9	n (%)	Total Charges	Mean Charges (SD)
Fractures	27 (24.3%)	$389,118	$14,966 ($13,693)
Intracranial injury, excluding those with skull fracture	9 (8.1%)	$98,414	$10,934 ($6,369)
Internal injury of chest, abdomen, and pelvis	20 (18.0%)	$557,560	$27,878 ($27,789)
Open wound of head, neck, and trunk	28 (25.2%)	$372,074	$13,288 ($21,130)
Open wound of upper limb	11 (9.9%)	$60,864	$5,533 ($4,501)
Open wound of lower limb	10 (9.0%)	$37,790	$3,779 ($1,451)
Injury to blood vessels	5 (4.5%)	$139,005	$27,801 ($21,603)
Other	1 (.9%)	$1,862	$1,182 (N/A)
Total	111 (100%)	$1,662,706	$14,979 ($19,234)

Severity and Discharge Condition: Seventeen (15%) of the patients died. Six of the patients who died had fractures, seven had intracranial injury, excluding those with skull fracture, three had an internal injury of the chest, abdomen, and pelvis, and one had an open wound of the upper limb. Four of the 111 patients sustained disabilities between a moderate level retaining the ability to perform self care to severe disability requiring dependence for self care upon discharge. Therefore, ninety (81%) of the gunshot wound patients were discharged in good condition, with previous level of functioning.

Outcome predictors: Table 2 summarizes linear regression results. The best predictors of length of stay, charges, and discharge condition were the type of injury (ICD-9), with sociodemographic variables, or alcohol and drug usage not contributing to the explained variance. Seventeen per cent of the variance in length of stay and 14% of the variance in charges were explained by having an internal injury of the chest, abdomen, and pelvis. Thirty-two per cent of the variance in discharge condition were explained by an intracranial injury, excluding those with skull fracture and fractures.

Table 2. Variance in LOS, Charges, and Discharge Condition for firearm-related hospitalizations for Travis County residents at Brackenridge Hospital, 1995.

Dependent Variable	Predictor Variables	Adjusted R Square	Standard Error of the Estimate
Length of stay	Internal injury of chest, abdomen, and pelvis	.17	5.28
Charges	Internal injury of chest, abdomen, and pelvis	.14	$17,408.48
Discharge Condition	Intracranial injury, excluding those with skull fracture, fractures	.32	1.16

DISCUSSION

This study utilized retrospectively collected data on firearm-related injuries during a one-year period, from January 1, 1995 to December 31, 1995, at Brackenridge Hospital Trauma Center. The sociodemographic profile findings in this study are very similar to profiles reported by other investigations (6, 8, 9, 11-14, 20-22, 25, 28, 29). Across these studies, a disproportionate number of the gunshot wound patients are men, young, and minorities. Eighty-seven per cent of the patients in this study are males, compared to only having 50% males in the general Travis County population for 1995 (30). A similar two-year study conducted in Travis County from 1991 through 1992 also reported 87% of hospitalized gunshot wound patients were male (31). The percent of male gunshot wound victims is consistent with previous studies in which 81% to 96% were males (6, 11, 12, 21, 22, 25, 28, 29).

Compared to the previous Travis County investigation for the years of 1991-1992, there was an 11% increase in firearm hospitalizations for patients aged 15 to 19 years, rising from 25% to 36% (31). There was also a 24% increase in the number of patients between 20 and 24 years. Overall, 60% of the patients were between 15 and 24 years of age. Fiedler, et al. (22) reported 73.5% of their gunshot wound patients to be between 15 and 35 years. In national estimates, Annest, et al. reported 120 per 100,000 of the firearm-related patients to be aged 15 to 24 years (6). Additionally, the CDC reported firearm injuries for Americans aged 10 to 34 years to be the second leading cause of death (14).

While the Travis County general population for 1995 was reported to be 62% Anglo-American, 11% African-American, and 24% Hispanic, the patients distribution this study found is 31% Anglo-American, 30% African-American, and 35% Hispanic, thereby confirming that minorities suffer a disproportionate number of gunshot wounds. Numerous other studies also report African-American and/or Hispanics to be disproportionately represented from the general population for non-accidental injuries, including gunshot wounds (6, 8, 9, 13, 20, 21, 25, 29).

Since assessments of alcohol and illegal drug presence at the time of admission were at the physicians' disgression, results must be interpreted cautiously with regard to a relationship with firearm-related injuries. Forty per cent of the 111 patients in this investigation had a measurable blood alcohol determination and 18% were legally intoxicated, with a blood alcohol concentration >100 mg/dL. Fourteen per cent were positive for tetrahydrocannabinol (THC) (100 mg/dL) and 11% were positive for cocaine. A study at the Harborview Medical Center in Seattle reported half of their 402 patients for non-accidental injuries had a measurable blood alcohol determination and one-third of the 358 assault victims were legally intoxicated (blood alcohol concentration >100 mg/dL) (8). Also, 76% of the 624 assault victims at the Harbor-UCLA Medical Center in Los Angeles had a blood alcohol determination in a two-year investigation (10). It is clear many patients of non-accidental injuries including gunshot wounds, present with alcohol consumption, and sometimes drug usage. However, the most accurate assessments can only come from consistent testing among all gunshot wound admissions. It was not explored whether these values reflect the alcohol and drug usage within the general population.

Of the 111 patients in this study, seventeen died. Thirteen (76%) of these deaths were attributed to some type of gunshot wound to the head. More specifically, seven were intracranial injuries without skull fracture. Although not investigated, this may lead to the suspicion of suicide or intentional execution at a close range. Linear regression analysis for variance in this study demonstrated the primary predictors for discharge condition, including death, were sustaining an intracranial injury without skull fracture or a gunshot wound that resulted in a fracture on any anatomic region of the body. These two factors attributed to 32% of the variance for discharge condition. A study by Klein et al. (10) reported one-fifth of their deaths related to intentionally assaulted victims were caused by cranial trauma. Similarly, Fiedler et al. (22) found that among the 45 patients in their study that had a gunshot wound to the head and neck, one-fourth died. These findings demonstrate firearm injuries to the head are often fatal.

The average length of stay for the 111 patients in this investigation was 4.67 days per patient, with a range of 1 to 30 days. This average is low considering other studies reported between 5.7 to

BEST COPY AVAILABLE

11 days average length of stay per patient for gunshot wound injuries (11-12, 20-22, 31). The average length of stay for gunshot wounds during 1991-1992 in Travis County was 6 days (31), as compared to 1995, a 22% decrease in length of stay occurred. It would be interesting to have data from 1993-1994 for a longitudinal analysis of length of stay trends in Travis County. A gunshot wound to an internal portion of the chest, abdomen, and pelvis predicted 17% of the variance for length of stay. Sociodemographic factors, alcohol and illegal drug usage, and type of medical insurance were not significant predictors for the variance in length of stay.

A 1990 article in *Time* reported for Americans under 65 years, 75% have some type of medical insurance (10). However, many investigations about non-accidental injuries, including gunshot wounds, report a very large proportion of the victims to be uninsured or publicly funded (4, 8-10, 21-25, 27-29). This study found 66% of the patients to be publicly funded or without funding of any kind. As a result, $1,056,000 of the total $1.66 million is left to the taxpayers. Bear in mind, these sums of costs only reflect medical costs to the hospital and are not including physicians' fees, physical therapy, hospital readmissions, rehabilitation services, lost wages, disability settlements, and legal fees. These additional costs plus hospital costs reflect society's financial burden from gunshot wounds and represent an immense economic impact. Although the average length of stay for 1995 was 22% less than 1991-1992, costs increased significantly. While the 1991-1992 average per patient was $10,300 (31), the average for 1995 was $15,000, demonstrating a 31% increase. The financial consequences to society and trauma centers from gunshot wounds are taking their toll. Dr. Arthur Kellerman, director of the emergency department at the Regional Medical Center in Memphis, Tennessee said, "The current situation in emergency departments can't continue without something breaking...This is a full-blown, certified crisis" (5). Nelson et al. poignantly explained, "Unfortunately the firearm is so ingrained in the American experience that one must conclude gunshot injuries and fatalities are simply a part of the cost of living in America today" (13).

This study better defined the sociodemographic profile and financial scope of hospitalized gunshot wound patients in Travis County, Texas during 1995. The results can be used as a tool to compare with previous and future studies in Travis County to improve the situation on a local level, as well as to compare to similar studies across the nation.

ACKNOWLEDGMENTS

The author wishes to express her tremendous appreciation to Dr. L. Michele Issel for her many hours of assistance, guidance, and support. Also, she thanks Kim Miller, RN and Steve Janda, RN at Brackenridge Hospital for their assistance in data collection.

Family Caregivers' Perceptions of Pallidotomy Surgery
Expectations, Satisfaction, and Health Dysfunction

Polly K. O'Brien

Dr. Jane Backer

Pallidotomy surgery may improve everyday functioning of persons with Parkinson's disease (PD) and thus, decrease the care demands on family caregivers. No studies have examined the family caregivers' perceptions of outcomes of the surgery. The purposes of this study were to: (1) describe the family caregivers' met expectations of the outcomes of pallidotomy surgery, and (2) describe the caregivers' satisfaction with the surgical outcomes. A secondary purpose was to compare caregivers' and patients' perceptions of patients' health dysfunction post-surgery and the extent of met expectations of and satisfaction with the surgical outcomes. The sample consisted of 10 patients and their caregivers (N=20). Findings indicated that caregivers were somewhat satisfied with the surgical outcomes and their expectations were partially met. Caregivers perceived a level of functioning similar to the patients with the exception of 3 areas where the caregiver perceived a lower level of patient functioning. There were no significant differences between caregivers and patients in the extent of met expectations of and satisfaction with surgical outcomes.

BACKGROUND

Parkinson's disease (PD) is a chronic illness that affects an estimated one in 50 people over the age of 60 in the United States (Field, 1991). PD is a life-altering condition rather than a life-threatening condition, that is characterized by impairments in movement, speech, balance, and swallowing (Duvoisen, 1991). Such impairments frequently result in the need for assistance from family members, especially spouses who are typically the primary caregivers. Family caregivers play an important role in providing health services for chronically ill individuals, such as persons with PD (Boland & Sims, 1996). However, care of the chronically ill person can have a negative impact on the caregiver, such as feelings of burden, personal strain, and social isolation (Boland & Sims, 1996).

The primary treatment of PD is drug therapy (Duvoisen, 1991). While drug therapy is initially effective in decreasing PD symptoms, over time the drug effectiveness decreases, resulting in the need for higher drug dosages and, concomitantly, the occurrence of drug side effects. Pallidotomy surgery is one of a very few treatment options available to individuals who no longer experience satisfactory relief of PD symptoms with drug therapy. The surgery, pallidotomy, involves inserting a probe into a very precise location of the globus pallidus of the brain and making a small lesion. Little has been published regarding the outcomes of this procedure, and no studies have focused on the family caregivers' perceptions of surgical outcomes. This study attempts to address the gap in knowledge.

The purposes of this study were to: (1) describe the family caregivers' met expectations of the outcomes of pallidotomy surgery, and (2) describe the caregivers' satisfaction with the surgical outcomes. A secondary purpose was to compare the caregivers' and patients' perceptions of patients' health dysfunction post-surgery and extent of met expectations of and satisfaction with the surgical outcomes. The findings of this study will provide information for family caregivers and health care providers about the potential benefits and problems of pallidotomy surgery from the family caregivers' perspectives and, thus, may assist nurses in helping patients in making decisions about whether to undergo the surgery

RELATED LITERATURE

Findings from research indicated that caregiving of chronically ill persons can have a negative impact on the caregiver, such as personal strain, social isolation, and depression (Biegel, Sales, & Schulz, 1991, Boland & Sims, 1995) Only two studies were found that specifically focused on persons caring for individuals with PD (Dura, Haywood-Niler, & Kiecolt-Glaser, 1990, Wallhagen & Brod, 1997) One study found that the caregivers of persons with PD experienced more depression than a comparative group without caregiving responsibilities on an interviewer rating of depression, but not on a self-report measure (Dura et al , 1990) Findings from the second study suggested that the negative impact of caregiving may be decreased by increasing symptom control (Wallhagen & Brod, 1997)

Whether pallidotomy surgery is effective in decreasing the symptoms of PD and thus, decreasing the negative impact of caregiving on the caregiver is not known as no studies were found that examined the outcomes of the surgery from the caregivers' perspectives One study by Backer (1997) focused on outcomes of the surgery from the patients' perspectives A prospective longitudinal design was used to study 22 patients with PD undergoing pallidotomy surgery The purposes of the study were to (1) examine the extent to which patients' expectations of the surgical outcomes were met, (2) examine changes in health dysfunction from the preoperative to postoperative periods, and (3) determine whether expectations met, health dysfunction, and demographic factors predicted patient satisfaction with surgical outcomes Findings indicated that more than half of the patients' expectations for the outcomes of the surgery were met and patients' health dysfunction significantly decreased Patient satisfaction increased as more patient expectations were met, patients experienced less emotional health dysfunction, and patients were better educated

In summary, there is empirical evidence that the care demands placed on caregivers of persons with PD may have a negative impact on the caregiver Findings from one study of persons with PD undergoing pallidotomy surgery suggested that the surgery may result in decreased demands on caregivers No studies were found, however, that specifically examined the outcomes of pallidotomy surgery from the caregivers' perspectives

METHOD

Sample The convenience sample consisted of 10 patients with PD who received a unilateral, stereotactic pallidotomy, and their spouse caregivers (N=20), age 45 to 71 years (mean= 61 years, SD= 8 21) The sample was obtained from a large, multi disciplinary study of patient outcomes of pallidotomy surgery There were six female and four male caregivers All subjects were Caucasian with the exception of one Asian American Only one subject reported less than a high school education, 11 had completed high school, 8 reported college or trade school education, and 3 had a college degree or higher

Instruments A revised version of the interview guide used with PD patients in the larger study was used in this study The interview guide consisted of open- and closed-ended questions that assessed the caregivers' expectations of and satisfaction with the surgical outcomes Demographic data (i e , the caregivers' relationship to PD patient, age, level of education, and race) were collected to describe the sample

The Sickness Impact Profile (SIP Bergner, Bobbitt, Carter, & Gilson, 1981) was used to measure patients' health dysfunction The SIP consisted of 136 items which assessed health dysfunction in 12 different categories Additionally, categories were aggregated into physical dysfunction, psychosocial dysfunction, and overall total SIP scores This measure has been used previously with PD patients and was found to provide a more comprehensive measure of functioning than PD-specific scales(Longstreth et al , 1992)

Procedure Data were collected by the investigator during a face-to-face interview Informed consent was obtained prior to the interview which took approximately 30 minutes to complete

Data Analysis Categories of caregivers' expectations of surgical outcomes were developed based on common themes A reliability check was performed by determining agreement between the investigator and mentor in the classifications of data Descriptive statistics were used to describe caregivers' expectations met and caregiver satisfaction The Kruskal-Wallis test was used to determine differences between caregivers' and patients' satisfaction with surgical outcomes and perceptions of patients' health dysfunction following pallidotomy surgery

RESULTS

Family caregivers' expectations of surgical outcomes were classified into the following categories (1)physical symptoms, i e , decreased sleep disturbances, less tremor, and less dyskinesia,(2)functional abilities, i e , improved walking, increased productivity, decreased falls, (3)changes in treatment, i e., stabilization of medications, (4)resumption of previous roles, i e , increased participation in household chores, and (5)other, i e , to improve in some way Most expectations of surgical outcomes related to physical symptoms and functional abilities The percent of caregivers' expectations met ranged from 33% to 100% (Mean= 77%) Although no significant differences between groups were found, there was a trend for caregivers to report a higher number of met expectations (Mean= 12 75) than patients (Mean= 8 25, p= 08)

Family caregivers reported being more than somewhat satisfied with the outcome of the surgery (Mean= 2 30, S D = 1 09) No significant differences were noted between caregivers and patients on level of satisfaction with surgical outcomes or perception of patients' total health dysfunction

Family caregivers and patients rated the dimensions of patients' health dysfunction similarly with one exception, ambulation dysfunction Caregivers rated patients ambulation dysfunction significantly lower (Mean= 7 95, p= 05) than patients (Mean= 13 05)

CONCLUSIONS

The family caregivers in this study were more than somewhat satisfied with their respective family member's surgical outcomes following pallidotomy surgery In general, pallidotomy surgery met the majority of the family caregivers' expectations of the surgical outcomes This may have, in part, contributed to their satisfaction with the surgical outcomes In a sample of patients with PD who underwent pallidotomy surgery, Backer (1997) found that the more patients' expectations of surgical outcomes were met, the higher their satisfaction with surgical outcomes The caregivers expectations of the surgical outcomes mainly focused on improving patients' functional abilities and decreasing physical symptoms Caregivers and patients had similar perceptions of patients' health dysfunction with one exception, ambulation dysfunction, in which caregivers rated patients' ambulation dysfunction significantly lower There were also no significant differences between caregivers and patients on level of satisfaction with surgical outcomes

RECOMMENDATIONS

One limitation of this study was the small sample size Thus, the findings of the study cannot be generalized to the population at large Future studies need to include a larger and more representative sample of family caregivers of persons with PD

Living on the Health Care Drawing Board: An Analysis of the Availability of Health Care to Low-Income Families in Los Angeles

William Ortiz

Whittier Scholars Department
Whittier College
13406 E. Philadelphia St.
Whittier, California 90608

Faculty Advisors:
Drs. Leslie Howard and Cheryl Swift

Health care reform is central to the U.S. agenda, but is in great need of improvement, especially in big cities like Los Angeles. Low-income families and ethnic minorities have little or no access to health care. Los Angeles County is attempting to implement a new health system in order to increase the likelihood of access to less costly primary and preventative care at community clinics. Under the new system in Los Angeles County, a number of clinics will close, further complicating the issue of health care access by increasing the distance to health care facilities for segments of the population. Using GIS, availability of health care services has been compared to demographic profiles of surrounding communities in an effort to assess the impact of the new health care delivery system in Los Angeles County.

> Everyone has the right to a standard of living adequate for

INTRODUCTION

Health preservation is essential to our everyday life. People go to great measures to assure themselves that they are in excellent health. Many families and individuals are pressed to find a way of maintaining good health for themselves and for their family members. Spector (1991) points out that human beings have resorted to different methods ranging from mágic and witchcraft to immunizations in an ongoing attempt to prevent sickness and maintain a healthy lifestyle. This process may include cultural rituals to prevent evil-eye[1] to undergoing intense chemotherapy to fight a carcinogenic tumor. These procedures arguably lead one to believe that everything is well, however, there are social and economic elements that affect an individual's health as much as biological and environmental factors. The World Health Organization (WHO) believes that health is much more than the absence of diagnosed physical disease, although the "medical model" of medical training tends to stress this aspect of health. The WHO recognizes that there are many natural as well as man-made factors that are responsible for an individual's health or lack thereof which contradicts what the North American health care provider has been socialized to believe: that modern medicine is the answer to *all* of humankind's needs and that only microorganisms are responsible for the illnesses people experience.

MATERIALS/METHODS

The study area presented and analyzed in this essay includes the cities located to the Southwest of the 2 and 101 Freeways, North of the 105 Freeway, East of the 405 Freeway as well as the ones West of the 710 Freeway[2]. (See Map 1) Most of the cities comprising the study area are made up of a variety of ethnic groups. The GIS and ArcView programs used in this research allow the author to create a spatial model of the location of the study area in relation to other cities. These computer programs also enable one to create spatial images of the statistics being analyzed. This is of extreme importance in order to provide the reader with a greater understanding of the information being presented and of the geographic location of each city within Los Angeles County. GIS and ArcView help to demonstrate the association between communities and the income of the people who reside in them. GIS and ArcView help in the design of maps that depict the study area in detail as well as the location of the clinics being examined.

RESULTS

The demographics of the study area as well as the location of the clinics serve to provide the reader with a greater understanding of the distinct groups from which Los Angeles County is made up. The 1990 Census data for Los Angeles County which clearly shows the areas in which the Latinos and African-Americans live; these are the two major ethnic constituents of Los Angeles County. The Anglos make up the remaining group represented in this study. For the most part however, the latter do not reside in low-income areas, and are not caught in the predicament of accommodating to the ever-changing, cost-rising world of health care since most of these individuals already belong to a health care plan.

---

[1] The evil-eye is primarily a belief that someone can project harm by gazing or staring at another's property or person. This belief is probably the oldest and most widespread of all superstitions, and it is found to exist in many parts of the world, such as Southern Europe, the Middle East, North Africa and Latin America.

[2] The Geographic Information System (GIS) and ArcView were used as tools to diagram the cities within the study area.

The cost of health care has risen every year. According to the Organization for Economic Cooperation and Development (OECD), people in the U.S. spent $2.868 on health care in 1991. Further, the OECD stated that in 1992 there were over 10 million children, 6 million unemployed, and 5 million part-time workers who did not have any type of health insurance. Today there are about 37 million people who are uninsured. Los Angeles alone has an estimated 2.6 million people in the county, most of whom are working, without health insurance with an additional 1.8 million residents on Medi-Cal. (Rabin, 1996) "A country's wealth should relate to the public's health, but the United States falls behind many industrialized nations that spend less money on health care." (Brown, 1989) Although some of these people may be serviced by private institutions or Health Management Organizations (HMOs), the main focus is on the role of the County's Health Centers in the delivery of health care to poor families and uninsured individuals. At the same time, it is believed that many of these individuals do not seek medical attention because they do not know where to go for affordable health care.

Even with all the changes that have taken place, low-income people are still victims of a private system that caters to the affluent. This is a system that is not attentive to the needs of poorer people who are experiencing distress. The lack of attention paid to patients is expressed in the form of sacrificing treatment for someone who cannot afford health care, and offering it to those who can. In spite of the fact that there are places where the needy may go for health care, they are still referred elsewhere when an emergency arises. In some cases, patients are not assisted on the basis that a language barrier exists or there is a lack of trained personnel due to government cutbacks on health care.

People also have to worry about making enough money to support themselves and their families. In many cases, these individuals fall under the poverty level, creating serious problems for maintaining health care. Even though this level rises constantly according to the economy of the country it does not mean that people's lifestyles are improving. "As of August 1990, the figures for a non-farm family of four was $12.600." (Hevesi, 1990) Families or individuals who fall beneath this line encounter a difficult time when it comes to making payments on a health plan in addition to their bills. The poverty line is defined so that the family income provides a satisfactory diet, without any regards to the other factors that affect an individual's health. It also depends on the size of each family and is modified each year to the consumer price index. (Spector, 1991) Dutton further advocates this idea by stating that:

> illness is disproportionately concentrated in the lower social class areas. There is a large gap between those at the bottom . . . and those at the top in nearly every measure of morbidity and mortality. . . despite the increased access provided by the public entitlement programs, the poor still have lower rates of utilization . . . fewer services at all ages relative to illness levels, less preventive care. . . and greater financial and organization barriers to access.

In short, not enough time and effort are being put in creating the blue prints for a system that will assist the underprivileged in attaining adequate health care. It also asserts that there is a low rate of utilization amongst the poor. This may be attributed to the lack of health centers in areas that have greater concentration of low-income families.

The County Health Centers as well as other health care providers in the 1990s are faced with a rapidly changing system of health-care delivery. A more technical and far less personal system has been created and it is nearly impossible for people with marginal incomes and no insurance to obtain the needed care. This is a major determining factor in the quest for health care since historically, poorer ethnic groups have not had the resources to acquire the medical attention they need. Most poor people live in substandard conditions, which pose numerous health risks such as: "rats, poisons, fires, inadequate heat and plumbing, dangerous electrical wiring, trash, deteriorated structures and crowding." (Brown, 1989; Rainwater, 1966) Living in these conditions give rise to serious health conditions such as stress, less opportunity to rest and recover as well as more vulnerability to infection due to structural and sanitary conditions of the environment in which they live. Even if "social class is measured by income, education, or occupation, much of the same pictures emerge: those at the bottom have the highest rates of death and disease." (Dutton, 1986) This is particularly true for individuals who are involved in strenuous activities that are required for work. This same population has transportation problems in accessing centralized health care. It is important to take notice that most of the County's Health Centers are located in proximity to one of Los Angeles major Freeways, the 110. At first glance one may surmise that they are readily accessible by means of private transportation, but the truth is that it is hard to get from one place to another in a city where *wearing a car* is a necessity if one wishes to survive. Sometimes it is difficult for people to receive the necessary care because they lack any type of transportation and cannot come up with the necessary fare to get from their homes the County's Health Centers and in some cases, from health center to health center and finally back to work or home. The rising cost of health care, the costly fee for transportation compounded with its slow pace, make it extremely difficult for individuals to receive immediate attention and adequate care when needed.

These incompetent methods of healing also affect the way in which people interpret and respond to the signs and symptoms of illnesses. Many people, especially those from developing nations, have their own ways of life and beliefs that are distinct from the ones to which North Americans are accustomed. These settlers from abroad continue to carry on their cultural as well as religious rituals used by their ancestors when faced with illnesses. As Spector (1991) states, this is true of immigrants from México, Central and South America and those from Eastern Europe. She goes on to say that these people "... share the problems and hopes and dreams of earlier immigrants and have their traditional health and illness beliefs and practices." This, however, is contradictory to what the Western health care provider believes and as a result, many people are turned away because of the cultural insensitivity expressed. Although the modern medical world may see these methods as rustic, it is up to the "modern" world to teach these individuals that there are effective alternatives to traditional methods of healing.

In some cases, people find themselves hoping for natural recovery, due to fear of being deported under Proposition 187: an inhuman bill denying needed medical, non-emergency services to undocumented people. This makes one wonder: What measures are being taken to prevent the spread of diseases such as TB or AIDS when people are not given the appropriate medical treatment? In the case of infectious diseases, individuals at high risk put others in danger of being wrongfully infected with a potentially fatal disease. Viruses and bacteria attack everyone regardless of whether these people are undocumented or not and Proposition 187 is a slap in the face of health care givers whose primary goal is to provide the best medical treatment to the masses without discrimination. This same concern was voiced by one of the Triage nurses at the Curtis R. Tucker Health Center in Inglewood, CA, whose patients are roughly 70% Latinos and 25% Blacks with few Asians being assisted throughout the year. She expressed her concern about living conditions of the patients who reside in the neighboring areas because many do not get tested for venereal diseases (VD) or for Tuberculosis (TB). She believes that Proposition 187 has had an enormous impact on the immigrant community who fear being deported if they try to receive medical care. This creates an even greater problem for the community because it means that the infected or "hot" patients are spreading diseases and are victims of a system that is unfriendly to the undocumented. This is especially true considering that many people tend to wait until the illness has become too complicated to prevent and sometimes do not receive adequate care because they are afraid of being victims of new laws that deny assistance to the poor and undocumented.

Phillips and Verhasselt (1994) are quick to add that there are also many examples of how economic development affects health status in a growing economy. On the one hand, there is an increase in "life expectancy, falling infant, child and maternal mortality rates and enhanced access to services". On the other, this type of "development" can cause many side-effects to the population in what Phillips calls the "health by-products" of industrialization. These "by-products" include: "... risks from new dangers at work, exposure to toxic substances, effluent radiation, traffic pollution and general industrial noise and waste in the environment. . . ." These people are the ones who typically find themselves the victims of inadequate care. As a result, there is a population of people not serviced by private health providers simply because these people cannot afford the ever rising cost of health care.

The number of Americans lacking health insurance has dramatically increased every year since the early 1980s due to the lack of availability. According to sources at the County's Health Centers, availability is a major factor in the health care world. It is true that the County's Public Health Centers offer cost-effective service to its patients, but the lack of government funding has forced several centers to downsize and cut down on the number of services offered as well as to reduce the number of patients seen per day. Phillips and Verhasselt (1994) state that:

> Recession. . .and debt servicing. . . have reduced public expenditure on health and welfare. The links between regional, economic and environmental factors and the health of a population are becoming clearer.

These factors have created a faulty system in Los Angeles County due to the lack of prioritizing as well as all the cutbacks with which the health system has been plagued. Moreover, one can see the results of the governmental cutbacks on the quantity of Health Centers left as well as the number of services they now offer to the poor and uninsured.

Downsizing has forced the County health providers to refer people to other potential health care providers (managed by HMOs) in the areas adjacent to the already existing health centers. This creates problems for the centers that remain open because it overloads their sites. In 1995, the Clinton administration allocated $16.6 million in gross appropriations to the County's Health Centers, but most of the original patients (and their friends) had already been snatched by the HMOs, which began servicing individuals who qualified for or already had Medi-Cal.

In turn, the loss of patients to the HMOs has a great effect on the number of patients who attend the County's Health Centers. In 1994-95, the number of outpatient visits was about 4 million, but when the centers began closing down, the number dropped to 3.2 million per year. With this in mind and the new contracting of the clinics, Los Angeles County officials estimate that in the 1996-97 period, there will be about 3.65 million outpatient visits. (Rabin, 1996) All these changes have put a strain on the patients who are now forced to find the needed care somewhere else until the County's Health Centers begin providing care for these patients once again.

The poor have recently encountered an even greater problem: the closure of several County clinics, which puts them in an even greater predicament. The poor are now constrained to the few

BEST COPY AVAILABLE

resources they have at home, thus putting them at greater risk of a serious illness or relapse. Some of the Health Centers have gone from being major providers of several services to simply offering one service, while others have received an excess of patients due to the closure of other centers. Even after all the downsizing, Los Angeles County health officials found a way of working together with private health institutions in an effort to balance public health with the ever-changing methods of providing adequate attention. This, however, puts a strain on the few County workers left as well as on the patients because they now have to rely on the expensive HMOs as their sole health care provider. The primary goal of HMOs is to keep prices down by limiting patient visits per year. This method, however, is not effective because should patients need further care they will only receive assistance at outrageous prices. This explains why there are many individuals without health insurance who are becoming victims of relapses when minor illnesses such as a cold become serious ones such as pneumonia.

County officials on the other hand, have made their services more available to some low-income individuals who may not have earned enough to afford quality care in the past. Some of the Health Centers that are still open provide services ranging from immunizations to TB testing. When emergencies arise the patients are referred to the nearest emergency ward, such as the Charles Drew Medical Center in South Central Los Angeles. In addition, some of the Comprehensive Centers offer semi-emergency services at their Urgent Care centers, which work as intermediaries between the outpatient clinic and the Emergency center. If an individual comes to the Comprehensive Center's Urgent Care Clinic, he/she is diagnosed and assisted according to the type of trauma from which they are suffering and transported to a neighboring Emergency Services provider.

Although the County clinics provide inexpensive health care to the poor and have ameliorated the health status of many poor individuals, they have not been enough to improve the well-being of the large population of uninsured people that has increased in the past few years. As of 1991 of all the industrialized nations, the U.S. and South Africa were the only ones without a comprehensive national health program. (Spector, 1991) As a result, county officials were hoping that by the end of the 1996 fiscal year, they would be able to double the number of outpatient clinics in the community from the present 39 to 83, "through the most extensive use of partnerships with private medical groups in the county's history. It is a dramatic departure from the traditionally separate public and private health care systems in the county." (Rabin, 1996) This would allow those uninsured individuals to obtain care at new, closer locations enabling workers to miss fewer days from work.

People are forced to rely on the County's Public Health Centers to receive care because most families qualify only for Medi-Cal; this is a federal-state type of assistance and it is available to individuals and families who meet the low-income criteria and are not covered by any type of health insurance. In an attempt to receive suitable care, some people have attempted to become part of an HMO-related health plan. This however, has not been of much benefit to those low-income people who are seeking professional treatment because they still face financial difficulties. Many of the people who have adequate documentation for return to the U.S., find it easier to drive to Tijuana, México to receive the same treatment for a lower cost from someone who speaks their language. County officials not expecting low-income patients to seek and find affordable health care in other countries, are now faced with the great deal of competition in the U.S. between private health care providers whose practices have caused an increase, rather than reduction in health care cost in Los Angeles.

Instead, County officials have created a system in which they will incorporate health care providers from the private sector. According to Luft, "the underlying notion of this type of competition is that people would be given a choice, usually on an annual basis, to choose among a set of health plan options to provide their care for the coming year." With all this in mind, one may have the misconception that the Health Center's services are free because of the fact that they cater to the less affluent, but one must realize that their services are provided at an affordable price for most, while others require further financial assistance.

CONCLUSION

Although the County health centers have been able to render their services to great numbers of poor and uninsured individuals, the cutbacks they have received along with the closure of some of these centers has made an enormous impact on how one views health care delivery. In addition to the lack of services and personnel at the clinics, one can clearly see that there are other underlying factors that prevent people from receiving the care they need. These factors, linked with the expansion of private clinics have prevented those at the bottom of the economic ladder from receiving health care because of their inability to pay such high prices for it. As the number of uninsured people increases due to the high prices of health plans, the quality of care diminishes at an astonishing rate.

Fathers, Food, and Fun: A nutrition Education Program for Low-Income Urban Fathers and their Children

Donald C Sweet, Debra Palmer Keenan, Ph.D., Lisa Gemlo, R.D., and Jennifer Ruffing

Department of Food Science and Nutrition
University of Minnesota

Faculty Advisor:

Debra Palmer Keenan

Low-income urban fathers constitute both an unserved population and a population in need. Nutrition education programs that focus on the specific needs of this group simply do not exist in the Twin Cities. We conducted focus groups with the target audience and designed a complete curriculum for nutrition education specifically for this group. This paper gives an overview of the design process and the resulting curriculum, with specific attention to a sample lesson covering food safety.

BACKGROUND

In recent years, Americans have become more aware of men's rights and family obligations. The Million Man March and Promise Keepers are two examples of this movement. In preparation for our research, we identified 19 support programs for men in general and 17 for fathers specifically in the Twin Cities. We contacted each of them, and none offered nutrition education. A nationwide literature search revealed only one nutrition program designed for fathers, and that was a program to educate fathers about the benefits of breast feeding. The changing structure of American households has led to an increasing number of single-parent families headed by fathers. Clearly, fathers are a population that could benefit from nutrition education.

METHODS

Local support programs for fathers were identified and the directors of these programs were invited to participate in focus groups. Two such focus groups were conducted with 14 participants. Questions were asked during these focus groups concerning their facilities, programs and participants. The program directors were also asked what age child presents the most difficulty to the fathers in their programs. Finally, the directors were asked for advice on what to cover in our upcoming focus groups with the fathers.

During a second series of three focus groups, 16 low-income fathers who lived in urban areas and participated in local support programs for fathers were asked about their opinions and attitudes toward nutrition and cooking, their motivation to participate in a nutrition education program, what they would like to learn, and what qualities they would prefer in an instructor.

Based on the results of these focus groups, a nutrition education curriculum was designed and implemented. The authors of the curriculum were available to the instructor for questions and revisions while the first two groups of participants completed the program. Revisions were made as necessary. Fathers enrolled in subsequent groups, as well as a group of control subjects who did not participate in the program, were asked to complete questionnaires before commencement and after completion of the program to measure its efficacy. Results of this evaluation will be reported at the annual conference of the Society for Nutrition Education this summer.

RESULTS

Fathers are motivated primarily by their love for their children. Some fathers saw a nutrition education program as a chance to spend quality time with their children. Fathers also felt they would be more likely to participate in a program that celebrated their culture, as well as others. Having fun was also a motivating factor.

Fathers were mostly interested in learning about basic and practical matters. Cooking skills, basic nutrition, food safety, and feeding their families within a limited budget were priorities. Also expressed was a desire to learn about different ethnic foods. The most frequently mentioned subject of interest was cooking.

Several concerns were brought up in the focus groups, such as transportation to and from the lessons and child care. Most stated that they would feel more comfortable if the lessons were taught at a location near their home by a male instructor, preferably a father, who was well-educated in nutrition. Many complained of receiving conflicting or incorrect nutrition messages from the media or health care professionals, suggesting that a trustworthy and well-educated instructor could help sort fact from fad. Others were concerned that not all participants would be custodial parents; they did not want fathers to be left out because they could not bring their children to the lessons. Very young children and teens were identified as the most difficult ages for parents to deal with.

Whether children should be present during instruction was a somewhat controversial issue. As stated earlier, some fathers viewed these lessons as an opportunity to spend time with their children. Others, however, preferred to learn the material first and teach it to their children themselves. They did not want the children to be a distraction, and some were worried about looking foolish in front of their children.

A complete and in-depth review of the results of these focus groups has been submitted to the *Journal of Nutrition Education*, and will be presented at this year's conference of the Society for Nutrition Education.

LESSON DESIGN

Six lessons were designed based on the above results. Each included fun, hands-on activities and food preparation, and each was planned to last two hours. Because very young children and teens were identified as being the most difficult ages for fathers to manage, the lessons were designed for fathers of children between the ages of four and eleven. It was felt that fathers of children within this range would be less likely to become preoccupied or distracted with problems associated with raising their children at the expense of their participation in the program. The six lessons are:

Five Alarm Chili:	*exploring the versatility of food, intro to Food Guide Pyramid*
Germ Warfare:	*food safety*
Play the Hand You're Dealt:	*meal preparation with scant resources*
Cooking with Power Tools:	*using utensils and following recipes*
Taster's Choice:	*exploring ingredients and taste preference*
A Child's Perspective:	*developing reasonable expectations for children's eating habits*

SAMPLE LESSON: GERM WARFARE

In this lesson, fathers learn about issues of food safety by participating in three activities: Safeburgers, The Smell Activity, and Mr. Jicama-Head. What follows is a description of this lesson, and not the actual wording in the lesson itself.

Safeburgers:

Participants work UV-fluorescent powder (representing germs) into a modeling compound (representing an uncooked hamburger patty). When this is done, the area is viewed under UV light. Glowing powder represents the transfer and spread of germs from the uncooked meat. Participants then clean their work surface, utensils, and their hands, and view the area again under UV light to see how effective their cleaning was.

The key points of this lesson are that germs spread from uncooked meat, and that hands, work surfaces, and utensils must be washed before and after coming in contact with uncooked meat.

The Smell Activity:

Participants are given cards with food safety scenarios printed on one side and a scratch-n-sniff label affixed to the other side. After reading the card and sniffing the label, participants will be engaged in a discussion about the particular concept of food safety represented in the scenario. Following is a typical scenario:

> "Dear-Ol-Dad and his children love chili. He usually makes very large batches of chili and keeps the leftovers in the refrigerator. This particular batch of chili was left on the counter from suppertime (6:00) until bedtime (10:30). Dear-Ol-Dad looked at the chili. It looked normal. It smelled like the label on the back of this card. Dear-Ol-Dad loves his children, and he would never do anything to risk their health, but food is expensive and money is tight. What should Dear-Ol-Dad do with the chili?"

The label on the back of the card smells like unspoiled chili.

The key points in this activity are that smell can be misleading and can not be trusted to determine the safety of a given food, and that knowledge is the best tool for determining a food's safety. Other points covered in this activity are that leftovers must not be left to stand at room temperature for more than two hours and that hamburger must be cooked at least medium-well before it is safe to eat.

Mr. Jicama-Head:

Participants break up into groups and prepare fresh, raw vegetables by washing, sorting, and cutting them. Pieces of vegetables are affixed with peanut butter to a large slice of jicama (also known as "Mexican potato") to form a face. The groups then display their creations before eating them.

The key points of this lesson are development of food preparation skills, proper washing technique, and discarding questionable food. Also stressed are the fact that children enjoy raw vegetables, which are more nutrient-dense than when cooked. Creativity and fun are encouraged.

The Germ Warfare lesson includes fun activities, food preparation, and food safety instruction, all of which were identified in our research as items our participants wanted. In addition, the activities can be done by the fathers with or without their children present.

CONCLUSION

Fun and active lessons and activities for low-income urban fathers and their children were designed based on research. To our knowledge, this is the first time such a program has been developed for this population.

This curriculum is currently being used in the Twin Cities by the University of Minnesota Extension Service, and it is expected to become available to other organizations in the near future. For more information, contact the authors at the above address.

ACCOUNTING FOR THE EFFECTS OF HURRICANE HUGO

Tulani Giscombe

School of Business
North Carolina Central University
Durham, North Carolina 27707

Faculty Advisor:

Mary Jones Phillips, Ph.D.

ABSTRACT

Hurricane Hugo blew into the Carolinas leaving hundreds of thousands of customers without power for up to two weeks. This research examined the effect of Hurricane Hugo on the financial statements of selected electric utilities. The methodology included accounting policy analysis and ratio and trend analysis. Policy choice centers on the issue of capitalizing versus expensing hurricane-related costs. The results show that capitalization had a smoothing effect on report income. Ratio analysis reveals a decline in key indicators such as the current ratio and debt/equity ratio.

INTRODUCTION

In September of 1996 Hurricane Fran slammed into coastal areas of North Carolina and into the Research Triangle Park (RTP) area where North Carolina Central University is located. The storm had eighty-five MPH winds when it hit the RTP. Tens of thousands of trees were downed; power lines and transformers were knocked out; and thousands of homes had structural damage. Electrical services were disrupted for up to fourteen days.

The storm had a devastating effect on coastal and piedmont North Carolina. Economic activity slowed as residents were unable to travel the streets and roads in the first days after the storm. As the roadways were cleared, economic activity increased above pre-storm levels.

This research examines how Duke Power Company, the largest electric utility in North Carolina, accounted for a natural disaster. Financial accounting for Hurricane Hugo, which occurred in 1989, was studied in order to have financial results for periods subsequent to the natural disaster and also to have published results for rate adjustment cases. Some of the questions investigated were: (1) Which costs from the storm were capitalized and which costs were expensed? and (2) What was the impact of the storm's costs on the company's income statement and balance sheet?

METHODOLOGY

Electric utilities are regulated entities. In this research, the rate-setting process for utilities is reviewed along with regulatory procedures for responding to a natural disaster. Regulatory accounting and Generally Accepted Accounting Principles (GAAP) are compared. The annual financial report and the notes to the financial statements were examined to determine how the companies accounted for the hurricane costs. Interviews were conducted with Michael C. Maness, CPA, Supervisor, Electric Section, Accounting Division, Public Staff, North Carolina Utilities Commission and with Cal Owens, Asset Accounting, Duke Power Company. Financial ratio and trend analysis were used to analyze the results of operations and financial position over a three-year period surrounding the event year.

UTILITY REGULATION

Public utilities in North Carolina come under the jurisdiction of several regulatory bodies including the North Carolina Utilities Commission (NCUC) and the Federal Energy Regulatory Commission (FERC). Companies that also operate in South Carolina are subject to regulation by the Public Service Commission of South Carolina (PSCSC). The NCUC and the PSCSC must approve rates for retail sales within their respective states. The FERC must approve rates for sales to wholesale customers. The NCUC seeks to set rates which allow utilities to recover reasonable costs and earn a reasonable return on investment.

Retail fuel costs are reviewed annually and during general rate case proceedings in North Carolina. In the wholesale and South Carolina retail jurisdictions, fuel costs are reviewed semiannually. Following such review, changes may be made in costs included in the base rates.

BEST COPY AVAILABLE

Utilities are allowed to adjust rates for past over- or under-recovery of fuel costs.

Policies established by state utilities commissions and the FERC determine how utilities account for costs associated with a natural disaster. Utilities must classify their costs by units of property. The FERC defines what the utility companies can consider a unit of property . It also prescribes the minimum level of units of property that a utility company is allowed to have and places a ceiling on the amount of units of property.

Costs associated with a natural disaster are capitalized or expensed based upon how these costs are categorized. If the item of property is not classified as a minor item, its costs are capitalized. Costs of minor items are expensed. However, the NCUC can and did permit Duke Power Company to capitalize expenses associated with the hurricane, by placing those costs in a deferred debit account. Duke Power Company was then allowed to amortize those costs over a five-year period.

RATIO AND TREND ANALYSIS

Ratios are benchmarks against which to evaluate a company's effectiveness. This study focuses on several standard ratios which are used in financial statement analysis including current and quick ratios, return on assets, return on average common equity, earnings per share (EPS), and debt ratio. Both industry comparisons and trend analysis were used.

The current and quick ratios measure a company's ability to meet its currently maturing financial obligations. (See Table 1.) The current ratio declined from 1.78 to 1.25 over the period 1988 to 1989. This deterioration in the ratio was due to a 48 percent increase in current liabilities while current assets increased by only 4.6 percent. The ratio declined slightly in 1990. As would be expected, the quick ratio also declined over the period from 1.21 in 1988 to 0.85 in 1989. It should be noted, however, that while Duke Power Company's current and quick ratios declined over the period, its ratios are significantly better than the averages for the industry.

Table 1: Liquidity Ratios

	1988		1989		1990	
	Industry*	Duke Power	Industry	Duke Power	Industry	Duke Power
Current Ratio	1.0	1.78	1.0	1.25	0.9	1.20
Quick Ratio	0.5	1.21	0.6	0.85	0.5	0.76

*Companies with assets of $250 million or more.

The return on total assets (ROA) shows the amount of net income earned in relation to total assets. This ratio is an indicator of how efficiently a company uses its economic resources. Duke Power Company's ROA declined by only 2.7 percent in 1989 but was down by 10.5 percent two years after the storm. The company again compared favorably with others in its industry. (See Table 2.)

Table 2. Profitability Ratios and Earnings Per Share* (EPS)
(in percent except EPS which is in dollars)

	1988		1989		1990	
	Industry**	Duke Power	Industry	Duke Power	Industry	Duke Power
Return of Assets	6.5	8.34	5.7	8.7	6.2	8.0
ROA - Common	4.7	13.4	2.4	14.7	4.7	13.1
EPS**	------	2.45	------	2.56	------	2.40

* Shown after stock split in 1990
**Companies with assets of $250 million or more.

Return on average total equity is a measure of the company's profitability. The ratios are higher than the return on total assets ratios, indicating favorable financial leverage. The ratios increased from 13.4 percent in 1988 to 14.7 percent in 1989. These ratios show that Duke Power

BEST COPY AVAILABLE

Company successfully used borrowed funds to earn a return greater than the interest paid on those funds. Therefore, stockholders benefitted.

Earnings per share (EPS) increased 4.5 percent over the year from $2.45 a share to $2.56 a share. However, EPS was down two percent over the two year period.

The debt ratio shows the percentage of total assets provided by creditors. (See Table 3.) It is an indicator of the long-run solvency and stability of the company. This ratio provides evidence of the safety of investments by bondholders and stockholders. Duke Power Company's debt ratio showed only a percentage point change over the 1988-1989 period, from 53.6 to 54.6 percent. As Table 3 shows, the contribution of debtors to the company capitalization was relatively constant for the periods reported. Again, Duke Power Company's ratios are significantly better than those for the industry.

Table 3: Stability Ratio (in percent)

	1988*		1989		1990	
	Industry*	Duke Power	Industry	Duke Power	Industry	Duke Power
Debt Ratio	62.1	53.6	62.3	54.6	58.4	54.7

*Companies with assets of $250 million or more.

SUMMARY AND CONCLUSIONS

Ratio and trend analysis show no effect of the hurricane cost on the profitability and financial position of Duke Power Company in the year of and the year following the storm. These results are attributed to the regulatory environment in which the utility operates. Utility accounting permitted Duke Power to capitalize $44 million and to treat an additional $19.5 million as deferred credits, essentially capitalizing those costs as well. The North Carolina Utilities Commission permitted the company to write the $19.5 million cost off over a five-year period. Included in the $19.5 million was $11 million cost of removing old units of property that were damaged or destroyed by the storm. Under current GAAP, nonregulated companies would have to expense those costs in the year incurred. The result of this treatment is to reduce the effect of the storm on the bottom line of the income statement and to increase reported assets on the balance sheet. In other words, the result is a smoothing of income.

FURTHER RESEARCH

This study has investigated the effect of Hurricane Hugo on the financial statements of one utility company. Historical data have been used. It would be interesting to see what the effects on the financial statements would be if nonutility accounting (current GAAP) had been used in accounting for the costs of the storm. It would also be interesting to compare the accounting by smaller companies with Duke Power Company's accounting for the cost of the storm. There may be differences in units of property capitalized and in the time period over which deferred credits were depreciated.

Faculty Advisors

Don Lisnerski, Bob Yearout, and Cheryl McClary

A study on the introduction to and use of smokeless tobacco in elementary age school children (Lisnerski, et al.) indicated that: 22.4% of children surveyed reported having tried smokeless tobacco at least once, while 5.72% reported continued use. This study received national attention from educators and the media. Since this study, educational efforts and state legislation have been changed to reduce or discourage the introduction and use of smokeless tobacco. The purpose of the follow-up study was to determine if these changes have been effective, and if there was a significant shift in demographics of underage users. The results of the follow-up study indicate a decrease in the use of smokeless tobacco products among children. This indicates that the changes in curriculum and legislation were effective in reducing the use in underage children.

INTRODUCTION

In the Fall of 1987 a study was conducted on the introduction to and use of smokeless tobacco in school-aged children (Lisnerski, et al.). Results indicated that: 22.4% of the children surveyed reported having tried smokeless tobacco at least once, while 5.72% reported continued use. Results also indicated that 36 percent of male rural first graders had tried smokeless tobacco, increasing to 70 percent by the seventh grade. Overall, rural males were more likely to have tried or be regularly using smokeless tobacco than were urban males or females. Other questions correlating with smokeless tobacco use indicated that it is predicted by three general concerns: a) perceived flavor, b) self-concept and presentation to peers, and c) family influence (Lisnerski, et al.). That study received national attention by educators and the media. Since that study, local educational efforts and state legislation have been changed to reduce or discourage the introduction and use of smokeless tobacco.

This follow-up study was done to assess the effects of a change in North Carolina legislation and a change in the school systems health education curriculum on smokeless tobacco use in school aged children. In a similar study conducted in Palm Beach County Florida, it was found that despite the enactment of state laws (October 1, 1992 and May 20, 1994), prohibiting the sale of tobacco to persons aged <18 years, 35 percent of minors were successful in making attempts to purchase smokeless tobacco (Bridges, Welsh, and Malecki, 1995). The same study was also conducted in Missouri and Texas. Even though laws were enacted prohibiting sale of tobacco to those under 18, 46.1 percent were successful in purchasing in Missouri. In Texas, 62.8 percent of minors were able to purchase tobacco products. These findings are being used to support legislation for stronger enforcement of laws and penalties to restrict minors' access to tobacco products (Romeis, Brownson, Davis, et al., 1993).

National surveys of adults indicate the highest prevalence of use now occurs among young adult males (Boyd, and Glover, 1989). According to a 1989 report of the U.S. Surgeon General, an 11-year-old girl in central Massachusetts achieved a 75 percent purchase rate of tobacco. Altman et al reported a purchase rate of 74 percent by minors aged 14-16 years in Santa Clara County, California. In Decatur, Illinois, Doctors Ought to Care (DOC) chapter reported a 63 percent rate of purchase for an 11-year-old girl and a 78 percent rate for a 16-year-old. Studies in Canada and England produced similar results, with a 79 percent to 87 percent purchase rate in Manitoba, and a 91 percent purchase rate by 16-year-olds in Avon,

England (Hoppock, and Houston, 1990) A study performed in urban public school students in Los Angeles and San Diego indicated the use of smokeless tobacco is more common among men than women and among Caucasians than African Americans, Hispanics, and others Twenty percent of the male respondents and 5 percent of the females reported use of smokeless tobacco at least once, 10 1 percent of males, and 3 1 percent of females who had never tried smokeless tobacco by seventh grade started to use it by eighth grade Among Caucasians, about 30 percent of boys reported trying smokeless tobacco at least once and 13 7 percent of those who had never used smokeless tobacco by seventh grade started experimenting by eighth grade (Hu, Hedeker, Flay, et al)

The 1987 study (Lisnerski et al) was vital in providing data on the relationship between age, smokeless tobacco use, and the demographic and attitudinal correlates of smokeless tobacco use It has helped in the assessment of health risks and in the design of health education programs State laws have been brought into effect to help in the reduction of purchase of tobacco across the United States North Carolina state law, effective January 1, 1995, states that if any person shall knowingly sell, give away or otherwise dispose of, directly or indirectly, cigarettes, or smokeless tobacco products to any minor under the age of 18, he shall be guilty of a class 2 misdemeanor (The Department of Justice of the State of North Carolina, 1996) Changes in the health education curriculum have also been made to incorporate discussion considering the negative impact of tobacco on school children On August 11, 1995, the Federal Drug Administration (FDA) issued a lengthy proposal to regulate the sale and promotion of tobacco cigarettes and smokeless tobacco products to minors The proposal includes three categories of regulations The first being the prohibition on sales to people under the age of eighteen The second is to limit the ability of the industry to market their product The third is a proposal to establish a public educational program to help educate people about the harmful effects of tobacco (Zieve, 1996)

METHODS

The author slightly modified the two versions of the smokeless tobacco inventory used in the 1989 published study These surveys were administered to a total of 478 school children in western North Carolina The total sample was broken down by grade, sex, and rural or urban residence Included were 98 first graders, 120 third graders, 143 fifth graders, and 117 seventh graders There were 239 males, and 217 females, and 22 children who failed to specify gender on their questionnaires Rural residence children were designated by school districts with less than 153 people per square mile, n=234 and urban residence children by school districts with more than 1906 people per square mile, n=244 A stratified random sampling algorithm was used Appropriate rural and urban schools were identified and classes were randomly selected within each grade level until approximately equal sample sizes were attained for each combination of grade and residence

One questionnaire was administered orally to first graders, a written version was given to third, fifth, and seventh graders Several refinements were made in the questionnaire as a result of the change in North Carolina legislation and the school system's health education curriculum The resulting questionnaires consisted of three questions identifying gender, age, grade and 20 questions, for third, fifth, and seventh graders, asking about use of smokeless tobacco, attitudes towards smokeless tobacco, familial, peer-group, and role-model use, recent purchasing of tobacco products, recall of smokeless tobacco advertisements and awareness of health risks associated with the use of smokeless tobacco and cigarettes A shorter version with only 12 questions was administered to the first graders The new questions were tested to ensure clarity to the younger students A "don't know" response added to "yes" and "no," was still a part of appropriate questions on both questionnaires Guidelines were developed restricting teacher involvement in questionnaire administration to prevent response biases and evaluation apprehension on the part of the students It was emphasized throughout each session that the questionnaires were entirely anonymous, that names should not be written on the forms, and that responses cannot be traced back to the individuals

RESULTS

With the exception of questions on age, grade, and sex, subjects' responses on the questionnaire consisted of "yes," "no," and for some items, "don't know." Since the data is primarily categorical in nature, a parametric analysis must be approached with caution The basic demographics of smokeless tobacco use is provided and broken down by grade, rural or urban residence, and gender The use of multiple regression for this analysis was deemed unnecessary

BEST COPY AVAILABLE

because of its particular sensitivity to non-normal distributions and because list-wise deletion of subjects with missing data and "don't know" responses produced regression analysis with either too few questions included, or too few subjects.

Overall, 8.55 percent of the respondents reported having tried smokeless tobacco at least once, compared to 22.4 percent in 1987. For those who continue use, 2.48 percent was reported compared to 5.72 percent in 1987. These overall percentages were broken down by first, third, fifth, and seventh grades, rural or urban residence, and gender.

The percent of children who had tried smokeless tobacco (see Table 1) has overall decreased. Significant increases have come in the areas of rural males, decreasing from 48.9 percent in 1987 to 19.83 percent in 1997, and rural females, 20.0 percent to 2.73 percent. There were cases in which percentages from the 1987 study increased. In the first grade, urban males who have tried smokeless tobacco increased from 5.7 percent in 1987 to 15 percent in 1997. Also, urban females increased from 7.9 percent to 9.1 percent. In the third grade, the only increase in experimentation came in the urban males where 0.0 percent had tried in 1987 compared to 3.4 percent in 1997. In the seventh grade, 3.3 percent increased to 8.7 percent in 1997.

Table 1. Have Tried Smokeless Tobacco by Grade, Sex, and Rural or Urban Residence

Question 1. Have You Tried Smokeless Tobacco?
(percent answering "yes")

	Grade									
	First		Third		Fifth		Seventh		Mean	
	'87	'97	'87	'97	'87	'97	'87	'97	'87	'97
Urban Males	5.7	15	0.0	3.4	9.4	0.0	38.2	10.3	13.3	7.18
Rural Males	36.4	15.8	44.7	6.1	41.9	13.3	72.5	44.1	48.9	19.83
Urban Females	7.9	9.1	3.4	0.0	12.1	0.0	3.3	8.7	6.7	4.45
Rural Females	12.9	0.0	19.4	0.0	12.1	4.2	35.5	6.7	20.0	2.73
Mean	15.7	9.96	16.9	2.38	18.9	4.38	37.4	17.45	22.2	8.55

With respect to "still use" smokeless tobacco, the overall percentages decreased for each class of residence with the exception being the urban females who increased from 1.5 percent in 1987 to 2.8 percent in 1997 (see Table 2). Although there are decreases in continued use of smokeless tobacco, some increases in percentages have occurred. In the first grade, urban males increased from 2.9 percent in 1987 to 10 percent in 1997. Also, the urban females had a substantial increase in their continued use of smokeless tobacco. In 1987, 2.6 percent reported continued use while in 1997, 9.1 percent have been reported. For the seventh grade, there was only a slight increase in continued use among rural males from 20 percent in 1987, to a reported 20.6 percent in 1997.

In summary, the data concludes that since 1987 overall experimentation and continued usage of smokeless tobacco has decreased. Individual increases in "have tried" smokeless tobacco occurred in the urban male and female first graders, urban male third graders, and urban female seventh graders. In the case of "still use" smokeless tobacco, the overall percentages decreased except for a slight increase in the urban female population. Individually, significant increases in continued usage occurred in urban male and female first graders, and also a slight increase in rural male seventh graders.

DISCUSSION

There appears to be a significant reduction in the trial and continued usage of smokeless tobacco in school-aged children. The only exception is male and female first graders. Their increase in experimentation and continued use may be a result of the fact that smokeless tobacco education does not begin until the third grade. It may also be a result of what is called magnet

schools which bring students in from a larger area instead of one neighborhood. This occurrence may allow for different samples to be over-represented or under-represented as compared to the 1987 study. School-aged children who report trying and still using smokeless tobacco also report having purchased it within the school year. This indicates that even though Legislation has been enacted prohibiting the sale of smokeless tobacco to those under the age of 18, children are still finding ways to purchase the smokeless tobacco products. Of the school-aged children who report trying and still using smokeless tobacco, over 71 percent report knowledge of the harmful effects resulting from continued usage. This shows that the current education curriculum is affective in giving knowledge of smokeless tobacco, yet some children continue their use.

Detecting Hidden Periodicities in Business Cycles of Fifteen Countries Using Fourier Analysis

Peter Hlavaty

Department of Economics & Business
Lafayette College
Easton, PA 18042

Faculty Advisors:

Edward Gamber and James DeVault

Business cycles reflect fluctuations in national income.Traditionally, business cycles have been examined for amplitude, length, diffusion and utilization rate. Little work has been done on the application of Fourier transforms to business cycles. This paper uses GDP data of fifteen countries to determine the structure of business cycles in the frequency domain. The structure is remarkably similar for all fifteen countries. Inverse transformation reveals that high frequency components are not correlated significantly, while low frequency components show very high cross country correlations.

BACKGROUND

Traditionally, business cycles have been examined for amplitude, length, diffusion and utilization rate. This paper focuses on the length aspect of business cycles. Various authors explored the length of business cycles (Valentine and Ellis, 1991; Diebold, 1993; Diebold and Rudebusch, 1991). None of them have attempted the Fourier analysis of business cycles.

National Bureau of Economic Research (NBER) defines the business cycle from a broader set of indicators of business activity than just the components of aggregate measures such as GDP. Relevant studies use predominantly the NBER definition of business cycles. Diebold (1993) showed that long expansions are followed by short contractions. He postulated that an economy gains an upward momentum during a long expansion and this momentum than mitigates the downturn. Diebold and Ellis (1991) showed that the duration of expansions and recessions in the US has significantly changed after the Second World War. The average length of an expansion increased from 25 to 50 months while the average length of recessions fell from 20 to 10 months. Valentine and Ellis (1991) tabulated the length of American business cycles between 1854 and 1990 and found out that most business cycles last between 3 and 4 years.

The above studies primarily deal with the US economy. They focus on cycles measured from trough. Such analysis assumes that the spectrum of country's business cycle is a horizontal summation of individual cycles marked by expansions and recessions. This paper, however, assumes that country's business cycle is a vertical summation (superposition) of individual sinusoidal cycles marked by different wavelength and amplitude/

METHODS

There is no consensus about how to define the business cycle. The NBER uses a complex definition of the business cycle in terms of various indicators of business activity. More simple definitions use only aggregate measures such as GDP. To obtain business cycles, one can use a decomposition of GDP data into a trend and a cycle or first - differencing method is outlined in Equations 1 through 5, where GDP_T is the trend component C is the cycle component.

$$GDP = (GDP_T)(C) \tag{1}$$

$$ln(GDP) = ln(GDP)_T + ln(C) \tag{2}$$

$$ln(GDP)_{t-1} = \alpha + \beta(t-1) \quad (3)$$

$$ln(GDP)_t = \alpha + \beta t \quad (4)$$

$$ln(C) = ln(GDP_t) - ln(GDP_{t-1}) = \beta \quad (5)$$

Fourier analysis of a time series is a decomposition of the series into a sum of sinusoidal components. For a periodic function f(x) with period 2a, the Fourier transform is given by (6). The right hand side of (6) is called the Fourier transforms of f(x). Coefficient a_n and b_n are called Fourier coefficients.

$$F(x) = a_0 + \sum[a_n\cos(\pi nx/a) + b_n\sin(n\pi x/a)] \quad (6)$$

When dealing with a nonperiodic discrete set of data, one has to adjust the mathematics to account for the nonperiodicity. The discrete Fourier transformation J_j of the data is given by (7). The Fourier frequency f is given by (8). The fast Fourier transformation is an algorithm for calculating the discrete Fourier transformations at all discrete frequencies using relatively few arithmetic operations.

$$J_j = n^{-1}\sum x_t\exp(-if_jt) \quad (7)$$

$$f_j = 2\pi j/n \quad (8)$$

The Fourier transformations can be then normalized with respect to their sum. As a result, percentage importance of each coefficient can be obtained. Finally, one can obtain wavelengths of the sinusoidal waves by inverting the frequency.

Annual GDP per capita data are used. The data are adjusted for inflation and are available for the following fifteen countries : Australia, Austria, Belgium,Britain, Canada, Denmark, Finland, France, Germany, Holland, Italy, Japan, Norway, Sweden and the USA. The economies of all fifteen countries are market based and therefore suitable for comparison. The data cover the period from 1900 to 1987.

Business cycles were obtained using the GDP data for all countries using Equations 1-5. The business cycles were then Fourier transformed. The Fourier coefficients were normalized with respect to their sum. The high frequency coefficients representing sinusoidal waves of short wavelengths were separated from the low frequency coefficients representing sinusoidal waves of long wavelengths. In particular, four categories were established: (1) Sinusoidal waves lasting 2-5 years, (2) 5-10 years, (3) 10-15 years (4) 15 and more years. The Fourier coefficients pertaining to each category were summed. Note that their sum represents the percentage importance of that category. The summations were compared across all fifteen countries.

Next, coefficients pertaining to each category were inverse transformed. The inverse transformations of each category were correlated across the same category for all fifteen countries. Finally, the cross correlations for each category were compared for all countries.

RESULTS

Figure 1 shows a business cycle for the UK and Figure 2 shows its Fourier transformation. Table 1 summarizes the main features of the Fourier transformations of business cycles for all fifteen countries.

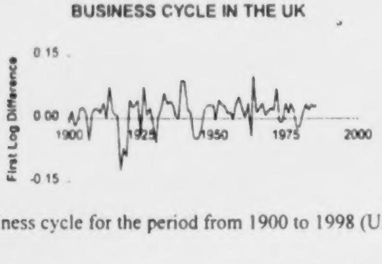

Figure 1: Business cycle for the period from 1900 to 1998 (United Kingdom).

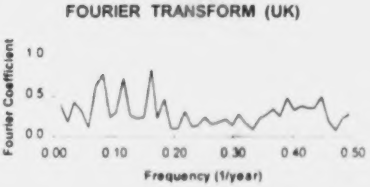

Figure 2: Fourier transform of the UK business cycle (1900-1987).

Table 1 : Percentage importance of sinusoidal components in business cycle structure for various countries.

Country	*2-5 years*	*5-10 years*	*10-15 years*	*15+ years*
Australia	57.3	22.7	10.4	9.6
Austria	42.8	33.3	8.9	14.7
Belgium	56.1	20.7	10.0	13.2
Britain	49.7	26.2	12.8	11.2
Canada	44.5	28.0	13.2	14.3
Denmark	61.8	19.1	8.2	12.0
Finland	53.6	24.1	10.5	11.8
France	55.9	17.0	13.0	14.1
Germany	61.5	21.5	8.9	8.1
Holland	54.6	24.8	9.5	11.1
Italy	50.6	24.9	11.5	13.1
Japan	57.4	18.8	9.3	14.5
Norway	62.4	19.2	7.3	11.0
Sweden	55.4	20.2	8.8	15.6
USA	48.6	29.4	9.1	12.8

CONCLUSION

The importance of sinusoidal components with various wavelengths is as follows: 2-5 years (54%), 5-10 years (23%), 10-15 years (10%) and 15 and more years (13%). These percentage values are averages for all fifteen countries. These results imply that the most important frequency components last between 2-5 years.

The zero lag cross country correlations of business cycles vary between -0.33 and 0.81, with an average of 0.22 and standard deviation of 0.27. However, the zero lag cross country correlations of inverse transformed low frequency components (15 and more years) are extremely high. Their average is 0.93 and their standard deviation is 0.11. In other words, long lasting sinusoidal cycles in the business cycle structure are highly correlated across all fifteen countries.

RECOMMENDATIONS

Alternative methods of deriving business cycles should be used to compare the final results. Also, a rigorous treatment of noise should be performed by filtering the initial GDP data. Finally, the use of wavelet transforms could be explored.

ACKNOWLEDGMENT

The author wishes to thank professor Edward Gamber for motivation and guidance during the preparation of this paper and professor James DeVault for supporting me along the way.

Effects of Foster Care on Perceptions of Family And Family Functioning

Judy Meyer

Department of Family and Consumer Sciences
University of Nebraska at Kearney
908 W. 25th
Kearney, NE 68849

Faculty Advisor:

Dr. Beverly Curry

There has been conflicting data about the ability of children who grew up in foster care to function as adults. This study explored the perceptions of family and levels of family functioning of adults, who as children, were in foster care. Significant differences were found in the areas of income and education levels, as well as in perceptions of family.

BACKGROUND

"In a statistical sense, the American family is the most violent social institution in our society" (Olson & DeFrain, 1994, p. 486). This recognition of family violence has led to the creation of laws that are intended to protect our children. For years we have taken children out of unsuitable homes and placed them in substitute foster homes. There was little research on the effects of this family substitution, either short- or long-term. Multiple placements were common for foster children, which created inconsistent views of family. These views, which were carried over into adulthood, had consequences that were not well known.

According to Flynn (1994), some children placed in foster care can become confused about three family-related areas. They can be confused about the nature of a family, about the biological family they left, and about the foster family in which they were placed. This confusion about boundaries and family structure may affect the child's psychological adjustment to foster care and their family relationships. Family environment, which provides the foundation on which future relationships are built, has been correlated to the mental health of children (Kashani, Canfield, Borduin, Soltys, and Reid, 1994). For example, if a child's perception of family support is low, that child is more likely to have behavior problems. Knowing these two things raised the question of how unstable familial foundations and a confused sense of family evolved and affected children in adulthood.

In 1978 Fanshel and Shim found that the quality and frequency of contacts with the natural family were closely correlated with the child's adaptation to foster care (Flynn, 1994) Distorted perceptions of the natural parents were found to occur with children who had infrequent visits with their parents. This was played out in two ways, over idealization of the parents or exaggeration of their parents' problems (Flynn, 1994).

When children rated family functioning of their natural families and foster families, natural parents were rated as healthy 50% of the time, while foster parents were rated healthy 80% of the time (Kufeldt, Armstrong & Dorosh, 1995). In this study, Kufeldt et. al. (1995) found that children do not idealize their parents when there is no contact. In a 1996 study, Gardner found that most of the children in foster care identified their foster family as their "family," instead of their biological family. Gardner's conclusion was that foster families were viewed as similar to biological, intact families in structure and were the ones with which children identified most.

A number of sources suggest that children in foster care have difficulties with psychological maladjustment, although this has been challenged by other studies. Marcus (1991) also suggested that children are at risk for insecure attachments, which may cause ineffective functioning as adults. One of Marcus's findings indicated that the quality of attachment to foster parents was the primary predictor of children's problems rather than their attachment to natural parents. Additional studies have shown that children in foster care had poor academic performance and low self-esteem (Johnson, Yoken & Voss, 1995).

Only a few studies have dealt with adult functioning specifically (Benedict, Zuravin & Stallings, 1996; Gardner, 1996; Mangine, Royse, Wiehe & Nietzel, 1990). Studies by Susser, Lin, Conover & Struening (1991) and Mangine, et. al. (1990) discovered that adults that had been in foster care as children were in the homeless population up to four times as often as in the general population. Susser et. al. (1991) reported that 79% of state hospital patients who had been in foster care as children reported being homeless at some time since the age of 17. Children in foster care run a much greater risk of adult dysfunction and homelessness.

Conflicting reports, however, state that former foster children are very similar to adults raised in natural homes in terms of socioeconomic situations, living conditions and the ability to function independently (Lyman & Bird, 1996). Johnson et. al. (1995) state that children formerly in foster care were able to function adequately as adults and were satisfied with the primary relationships in their lives.

SAMPLE

Participants in this survey were age 19 or older. Those in the foster care group had to be in foster care as a child, and had to respond to an ad in the paper or to posters that were distributed to the University of Nebraska-Kearney campus and two employment agencies. Snowball sampling was also used. Persons who responded to the ads were asked if they knew anyone else who was in foster care as a child. Once this information was obtained, the respondents names were looked up in the phone book. The persons whose names appeared directly above and directly below that name were also sent a survey, thus creating the control group. Mail survey design was used.

Two well-known questionnaires, a modified version of the Family of Origin Scale (Hovestadt, Anderson, Piercy, Cochran, & Fine, 1985) and the FACES II scale (Olson, Bell, & Portner, 1991) were used in this study. The Family of Origin scale was modified to elicit responses that pertained to families in general rather than family of origin. FACES II was used to gain information about current family functioning. Family was defined as anyone that the participant saw as being in their family.

RESULTS

In all, 31 questionnaires were received. Of the 31 respondents, 14 had lived in foster care. The average age of respondents in the foster care group was 30.21 years. The average age of the non-foster care group was 48.25 years. There were very few differences between the two groups in terms of demographics, with the exception of two areas: education level and yearly income.

In terms of yearly income, the foster care group was significantly weighted in the lower income levels. All but three persons in the foster care group earned less than $20,000 annually. No one in this group had an income of $40,000 or above. The non-foster care group had 9 persons in the $40,000+ category. (See Figure 1).

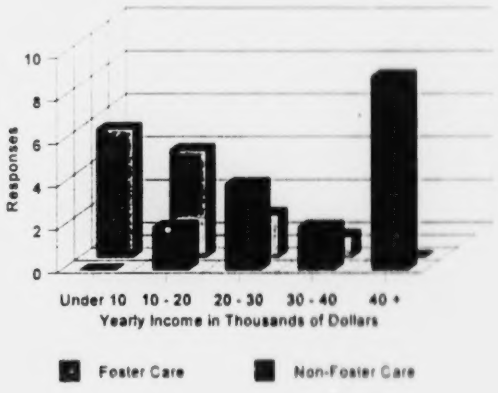

Figure 1: Yearly Income for Foster Care vs. Non-Foster Care Participants

The majority of the participants in the foster care group had graduated from high school or attended some college. The non-foster care group was more evenly distributed along all levels of education. The "didn't graduate from high school" category did not have any responses and the "Ph.D." category had four responses from the non-foster care group. (See Figure 2)

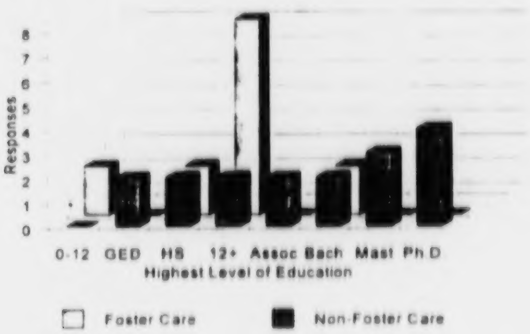

Figure 2: Education Levels for Foster Care vs. Non-Foster Care Participants

The modified Family of Origin Scale, which assessed the perceived health of families in general, showed a significant difference on the Likelihood Ratio of .050. Only five of the 14 persons in foster care viewed families in general as healthy, while 12 of the 17 non-foster care participants viewed the health of families in general as high. Sixty four and three tenths percent (64.3%) of foster care respondents perceived the health of families in general as low compared to 29.4% of non-foster care respondents. (See Table 1).

Table 1: Perceptions of Family in General

	Foster Care	Non-Foster Care	Total
Health Perceived as High	5 35.7%	12 70.6%	17 54.8%
Health Perceived as Low	9 64.3%	5 29.4%	14 45.2%
Total	14 100.0%	17 100.0%	31 100.0%

There was no significant difference between the foster care and non-foster care groups for current family functioning. Both groups were fairly similar in family types. (See Table 2).

Table 2: Levels of Family Functioning

	Foster Care	Non-Foster Care	Total
High Levels of Family Functioning	6 42.9%	8 57.1%	14 50.0%
Low Levels of Family Functioning	8 57.1%	6 42.9%	14 50.0%
Total	14 100.0%	14 100.0%	28 100.0%

DISCUSSION

There were several limitations to this study. The foster care group was limited in part to those persons who read the paper and were willing to call in response to the ads. This did not give persons who do not read the paper a chance to participate. This study was also not generalizable due to its small size and lack of representation of the population. The parameters of this study extended only to the number of responses received from the advertisements.

One major finding of the study was the significant difference between the income and education levels of the two groups. Foster care participants were less educated and earned less income annually when compared to the non-foster care participants. This finding may support the notion that children who were in foster care were not able to function as well as adults. These differences need to be explored further to confirm their validity. The perception of family scale also showed a significant difference between the two groups, although this difference was slight. There was also no significant difference on the family functioning scale, which indicated that persons in foster care were able to function just as well as those persons who never experienced foster care. Foster care in and of itself was not a predictor of adult family functioning. Further studies on family functioning and perception of family need to be conducted with larger sample sizes that more accurately reflect the population.

Retailer Country Bias Cues:
An Experimental Approach

Sherry L. Lotz, Ph.D.

A saturated home market is forcing U.S. retailers to look for opportunities abroad. Despite their competitive advantage over foreign counterparts, U.S. retailers have met with limited success. Thus, global retailers are in need of strategies and incite into foreign consumers' perceptions to strengthen their operations abroad. This research examines the effects of the retailer country of origin and merchandise type on Hispanic consumer evaluations utilizing a 2 x 2 between subjects factorial experimental design. The study's results indicate a significant effect for country of origin, with no significance for merchandise type. Specifically, U.S. retailers were evaluated more favorably than Mexican retailers in terms of atmosphere, service and terms of sale.

BACKGROUND

Oversaturated domestic markets are requiring U.S. retailers to look abroad for further opportunities. All major formats, from discount to department stores, are included in this race for global expansion. Yet, many of these retailers are running into obstacles in their ventures abroad (Treadgold, 1991). Major companies such as Woolco, Dillards and JCPenney are withdrawing from foreign markets, often with considerable losses.

Essentially, U.S. retailers require accurate factors upon which they can base their strategic planning (Segal-Horn and Davison, 1992; Treadgold, 1991). A crucial issue is whether to standardize the domestic program or to adapt the program specifically to the foreign market. This decision will be affected by cues such as country of origin upon which consumers base their evaluations of the retailer.

Research related specifically to consumer evaluation cues with respect to retailers is not widely available. Thus, research of international products provides the best foundation for investigating consumer evaluations of global retailers. This product research suggests that a product's country of origin may bias consumer evaluations which is a result of country stereotypes (Bilkey and Nes, 1982; Harris, Garner-Earl, Sprick and Carroll, 1994; Klenosky, Benet and Chadraba, 1996). This resulting bias can be positive or negative in nature depending upon the country image created by the informational cue.

As with products, the global retailer can also be assessed by consumers in terms of country of origin. This research investigates the effect of country of origin and type of merchandise on Hispanic consumers' evaluations of U.S. and foreign retailers. The questions explored in this research are as follows:

> Research Question 1: Does the retailer's country of origin affect the Hispanic consumer's evaluation of the retailer? If so, how are the assessments affected?

600

Research Question 2: Does the merchandise type affect the Hispanic consumer's evaluation of the retailer? If so, how are the assessments affected?

Research Question 3: Is there an interaction between retailer's country of origin and merchandise type on the consumer's evaluation of the retailer?

REVIEW OF LITERATURE

Country of Origin

Country of origin and product evaluation. The country of origin (COO) is an extrinsic product cue, like price or brand (Peterson and Jolibert, 1995). It is the product's source country, noted by the phrase, "Made in (name of country)." The COO is considered an informational cue by researchers, as it provides information to consumers for decision making purposes (Bilkey and Nes, 1982).

Country of origin effects, related to consumers' evaluations of products, have been extensively investigated. The main conclusion of this research is that consumers develop stereotypical images of countries and their products which bias their product evaluations. In 1982, Bilkey and Nes reviewed 25 country of origin studies which support this assertion. Research indicates that this country stereotype can result from a number of factors, including a consumer's experience with a product from a country, the country itself, political beliefs, etc. (Samiee, 1994).

Research suggests that there is a relationship between the country's level of economic development and consumers' product perceptions (Gaedeke, 1973; Kaynak & Cavusgil, 1938; Wang and Lamb, 1983). A product from a more developed country has been found to receive more favorable evaluations than a product from a less developed country (Schooler, 1971; Wang and Lamb, 1983; Cordell, 1992). In illustration, a stereo made in Japan (more developed country) may be evaluated more favorably than an identical stereo produced in Mexico (less developed country).

Similar research also indicates the presence of a "home country bias." This is the consumer's tendency to favor domestically produced goods (Bannister and Saunders, 1978; Lillis and Narayan, 1974; Nagashima, 1970). Studies link this bias to ethnocentrism, nationalism (Han, 1988; Shimp and Sharma, 1987) and a perceived risk in purchasing foreign products (Hampton, 1977).

Country of origin and product type. Country of origin research also suggests that country of origin and product type may combine to impact consumer assessments of products (Samiee, 1994). This result is rooted in the idea that consumers already hold beliefs with respect to product quality from various countries. Consumers regard favorably the product produced in a country with an affinity for the product. Conversely, consumers negatively regard the product originated from a country lacking such an affinity. For example, a favorable evaluation may be elicited for Chinese silk or French wine. In contrast, a poor evaluation may be produced for Mexican silk or Russian wine.

Country of origin and retailers. To date, only one study has been conducted on COO with respect to retailers. General results showed that more developed countries receive more positive evaluations as opposed to less developed countries, with the exception of a more favorable evaluation for less developed countries in terms of pricing (Lascu and Giese, 1995).

This study provided an initial confirmation that retailer country of origin does affect consumer perceptions. However, the country of origin was confounded with the merchandise type. In addition, the use of subjects solely from the United States limited the generalizability of perceptions of cross-country retailers by other cultures.

METHODOLOGY

Procedures

Data was collected from 43 volunteer subjects who were students or employees of a large Southwestern university. Participation criteria included requirements that the subject be of Hispanic descent, have lived at least one year in Mexico and be familiar with retailing in Mexico and the United States. Before completing the questionnaire, subjects were asked if they preferred the Spanish or English version of the measurement instrument. After the choice was given, subjects were asked to read a description of a hypothetical retailer noted by its country of origin (United States/Mexico) and its type of merchandise (denim jeans/handcrafted furniture). Furthermore, the description explained that the retailer would be opening stores in Arizona's metropolitan areas in the summer of 1997. After reading the description, subjects were asked to complete evaluative questions about their perceptions of the retailer's merchandise, service, advertising, etc. In addition, subjects answered several demographic questions pertaining to their age, educational level, etc. Upon completion of the study, subjects were given an offer to enter a one-time prize drawing for $50.00.

Experimental Design

The research encompassed a 2 x 2 between subjects factorial experimental design. The two factors were 1) country of retailer (U.S./Mexico) and 2) type of retail merchandise (denim jeans/handcrafted furniture). Therefore, the experiment included four treatment conditions: U.S./denim jeans; U.S./handcrafted furniture; Mexico/denim jeans; Mexico/handcrafted furniture. Subjects were randomly assigned to one of the four treatment conditions.

Questionnaire Development

Pretests and a focus group were conducted with Mexican consumers to determine which merchandise lines are perceived as favorable for the United States and Mexico and which lines are perceived as unfavorable. Answers indicated that Mexico is positively associated with the production of hand-crafted goods whereas the U.S. is highly regarded as a manufacturer of denim jeans.

In pretesting the measurement instrument, the questionnaire was administered to a small convenience sample of subjects meeting the experimental criteria in an attempt to reveal possible problems in wording, understanding, etc. Corrections were made as deemed necessary.

Two versions of the questionnaire were constructed, i.e., English and Spanish, in order to give subjects their preference of language. The English version of the questionnaire was transposed into Spanish and backtranslated into English to insure a direct, accurate rendering of the instrument.

RESULTS

Data Analysis

The data was analyzed using a Multivariate Analysis of Variance (MANOVA). Testing was conducted in order to assess differences in seven a priori store attribute factors: merchandise, service, atmosphere, terms, promotion, value and convenience. When indicated by a significant MANOVA result, individual Analysis of Variances (ANOVAs) were examined to assess specific differences. Both interaction and main effects were examined.

Interaction effects as well as merchandise line effects were nonsignificant. Thus, the sole significant MANOVA was retailer country of origin. In an examination of the significant country of origin effects, only factors relating to service (U.S. Mean=5.74, Mexico Mean=5.17, $F=3.35$, $p=.07$), atmosphere (U.S. Mean=5.88, Mexico Mean=5.11, $F=5.30$, $p=.03$) and terms (U.S. Mean=5.62, Mexico Mean=4.66, $F=8.98$, $p=.00$) were significantly different for evaluations of U.S. retailers as compared to Mexican retailers. Specifically, U.S. retailers were evaluated more favorably as compared to Mexican retailers with regard to the three retail attributes, i.e., service, atmosphere and terms.

Table 1 MANOVA and ANOVA Results on Retail Attributes by Country of Retailer Origin

	MEANS[1] (S.D.)			
Retail Attributes	U.S. (n=24)	Mexico (n=19)	Univariate F	Multivariate F
				2.68**
Merchandise	5.78 (1.23)	5.25 (1.20)	2.78	
Service	5.74 (1.10)	5.17 (1.24)	3.35***

CONCLUSION

The findings of this study reveal that stereotypes do exist for retailers based upon their country of origin, regardless of the retailers' merchandise line. As such, those retailers that cross borders should understand consumers' perceptions of their country of origin in order to enhance positive perceptions and negate unfavorable perceptions. For example, in this study, U.S. retailers were perceived to possess a more pleasant store atmosphere as compared to Mexican retailers. This result indicates U.S. retailers should pay careful attention to focusing on this aspect of their business in promotions, etc. On the other hand, U.S. retailers were not evaluated differently with respect to value. This could be quite problematic for U.S. discount retailers which enter the Mexican market emphasizing the "value" aspect of the business. Special campaigns might be needed in order to create a differential between the retailers and their competitors in regard to the value concept.

Matching Cultural Value Orientations to Ad Appeals: Exploring the Role of Individualism-Collectivism in the USA Versus Mexico

Past research suggests that cultural orientation individualism-collectivism should be considered when developing global advertising campaigns. Although numerous studies have examined cultural differences between foreign markets, few studies have measured how inconsistencies in value orientations presented in global advertising messages may affect consumer behavior. In research reported here, examined are how certain aspects of individualism-collectivism may affect attitudes and behaviors toward advertised products within the USA and Mexico. The data provides little support that individualism-collectivism matters across cultures, but it could matter within cultures. Interestingly, product category appears to be an important issue for future research on individualism-collectivism in consumer behavior.

INTRODUCTION

As multinational firms race toward globalization of markets, the issue of standardized versus customized advertising messages remains unresolved. Some marketers believe companies should consider standardizing ads to improve long-term profitability (Szymanski, Bharadwaj, and Varadarajan, 1993). Other researchers suggest that since no two cultures are exactly alike, the most effective ads are those developed for each individual market (Jain 1989; Wills, Samli, and Jacobs 1991). Therefore, the focal point of the research is to investigate the role cultural values may play in cross-cultural advertising.

Cultural values may play an important role in the perception of marketing communications. Studies examining message content indicate that one very important dimension of culture to consider when developing advertising and promotional messages is that of individualism-collectivism (Han, 1990; Kale, 1991; Zandpour, 1994). Past research also suggests that advertising themes that are consistent with cultural values of the target audience are more desirable than ads that reflect values that are inconsistent (Belk, Bryce and Pollay, 1985; Munson & McIntyre, 1978). In summary, consumers who possess collectivist values should favor ads which appeal to collectivist values, while individualist consumers should opt for individual ad appeals.

The Individualism-Collectivism Construct

One dimension of culture that closely relates to social behaviors within a society is individualism versus collectivism. The individualism-collectivism dimension at the cultural level relates to how one values the individual relative to the group. Individualist societies (U.S., U.K., Germany) emphasize values such as achievement, recognition, etc. (McCarty & Hattwick, 1992); collectivist societies (Mexico, Peru and Chile) emphasize values such as family security, responsibility, conformity to societal norms, etc. (Hofstede, 1980). Based on factor analysis, Mezei (1974) found that individualism-collectivism was the most important cultural dimension from a list of values studied by Kluckhohn & Strodtbeck (1961). This suggests that individualism-collectivism may be an important dimension to consider when communicating across cultures.

Although a culture may be largely individualist or collectivist, it is important to note that at the individual level a consumer may exhibit either individualistic or collectivistic tendencies. Prior research examining individualism versus collectivism at the individual level identifies persons who display individualist tendencies (e.g., emphasize personal goals over ingroup goals) as idiocentrics; and persons who display collectivist tendencies (i.e., emphasize ingroup goals over personal goals) as allocentrics (Triandis et al., 1990). American, as well as Mexican, cultural groups contain individuals that display both idiocentric and/or allocentric tendencies, depending on the behavioral context. On the other hand, Mexicans place a strong emphasis on family unity and cohesiveness. Mexicans tend to be more cooperative in interpersonal activities compared to their American counterparts (Diaz-Guerrero, 1982). A recent review of literature by Diaz-Guerrero & Szalay (1991) on Hispanic/Latin family values suggests that Mexican parents place a greater emphasis on parental authority, respect, obedience, affective interdependence and discipline in their children when compared to American parents. Consistent with general findings by Triandis (1989), Diaz-Guerrero (1967) found that Mexicans (as a collectivist society) displayed more unity than Americans (as an individualist society) with respect to the family, and are more willing to subordinate their individual priorities and interests to those of the family ingroup.

HYPOTHESIS

Based on review of the literature examining individualism-collectivism, consumers' cultural value orientations differ across cultures and these differences should affect their advertising preferences. Specifically, the first hypothesis:

> H1: Consumers in an individualist culture (USA) will prefer individualist relative to collectivist ad appeals. For consumers living in a collectivist culture (MEXICO), the reverse will be true. That is, collectivists will prefer collectivist ads compared to individualist ads.

The research examining idiocentrics and allocentrics suggests that irrespective of the overall cultural value orientation, differences in advertising preferences will be most evident when cultural values are considered at the individual level within one's culture. Therefore, consistent with H1:

H2 Idiocentric consumers will prefer individualist relative to collectivist ad appeals. This should be true for both the USA and MEXICAN idiocentrics. For allocentrics, the allocentrics will prefer collectivist ads compared to individualist ads.

METHODOLOGY

One hundred eighty-four undergraduate college students (USA, 112 UTA subjects, MEXICO, 72 Northern Mexico University subjects) were assigned randomly to a treatment. The subjects were then asked to evaluate an ad and complete a questionnaire. The questionnaire contained the following set of measures.

Attitude toward the Advertisement

Ad Attitude component was measured first and was assessed using three 9-point semantic differentials: good/bad; like/dislike; positive/negative. The coefficient of reliability was quite acceptable (alpha USA = .91; alpha MEXICO = .82).

Triandis 16-item scale used to measure individualism-collectivism

Triandis is used to measure individual-level differences across cultures.

Allocentric and Idiocentric Measures

Triandis is also used to examine individual-level differences within cultures.

Translation

The instrument used in this study was first written in English, then translated into Spanish by a native Mexican, fluent in English. The instrument was then backtranslated to English by a translator fluent in both Spanish and English to assure that a proper translation has taken place (Brislin, 1980).

Ad Pretests

The ad appeals were pretested to be certain that individualism-collectivism was in fact manipulated. The ad copy used to manipulate was as follows: There is a company that is building cars Safer for YOU! The copy used to vary collectivism stated: There is a company that is building cars Safer for YOUR FAMILY!

RESULTS

Hypothesis One was tested by examining the culture by ad appeal interaction on a measure of attitude toward the advertisement.

For the auto ad H1 was not supported (F(1,181) = .84, p = .359). Interestingly however, a main effect of culture was found (F(1,181) = 9.31, p = .003). Mexican consumers rated the auto ad more favorable (X = 7.0) than did the USA consumers (X = 6.15).

For the sunscreen ad H1 was also not supported ($F(1,181) = .02$, $p = .875$). Again, there was no evidence that matching the predominant culture orientation (individualism or collectivism) with ad appeal (individual or collective appeal) influences ad liking. Interestingly, however, for the sunscreen ad an ad appeal effect was found ($F(1,181) = 4.75$, $p = .031$). Irrespective of one's cultural value orientation, the collectivist appeal ($X = 7.17$) was preferred to the individualist appeal ($X = 6.65$).

The same approach was used to test H2. Namely, what should occur is an interaction effect to occur between idiocentrics/allocentrics and ad appeal (individual/collective). Also, USA and MEXICAN idiocentrics should like the individualistic ad better than the collectivist ad and, for USA and MEXICAN collectivists the reverse should be true.

First, the USA subjects were considered for the auto ad. H2 was not supported ($F(1,108) = .93$, $p = .336$). No other significant effects occurred. H2 also received no support from the sunscreen ad in the USA ($F(1,108) = .01$. $p = .997$). There was however, some tendency for both idiocentrics and allocentrics to prefer the collectivist sunscreen ad appeal ($X = 7.1$) to the individualistic approach ($X = 6.6$) ($F(1,108) = 2.88$, $p = .092$).

Next, the Mexican subjects were considered for the auto ad. Once again, H2 received little support ($F(1,69) = 1.85$, $p = .178$). No other effects were found. The test of the sunscreen ad like Mexico also rejected H2 ($F(1,69) = .93$, $p = .339$). Some weak evidence does suggest an allocentric/idiocentric effect on advertising preference. Allocentrics liked the sunscreen ad ($X = 7.2$) somewhat more than did idiocentrics ($X = 6.55$) ($F(1,69) = 2.53$, $p = .11$). Also, the pattern of means suggests that allocentrics in Mexico do favor the collectivist ($X = 7.6$) over the individualistic ($X = 6.8$) ad appeal (t = XXX, $p = .07$)

DISCUSSION

The purpose of this study was to examine how certain aspects of individual-collectivism may affect attitudes and behaviors toward advertised products within the USA and Mexico. The following was discovered:

1.) No evidence of individualism/collectivism match-up effect.
2.) Only weak evidence of allocentrics/idiocentrics match in Mexico.
3.) So what does this tell us? Well,
    Individualism/Collectivism may not matter in advertising appeals?
    Individualism/Collectivism is not used to evaluate ads.
    Advertising preference has little to do with Individualism/Collectivism.

4.) Perhaps it would be more interesting to begin to consider why we had differing effects across products. That is, the auto and sunscreen ads did generate different effects -- one showed culture effects; one showed ad appeal effects. Thus, the findings suggests that two very important cultural aspects to be considered when developing international advertisements: the cultural values represented in ads, and the variation in attitudes and behaviors towards ads as moderated by product category.

Future research efforts should continue to examine whether these relationships apply to other cultural domains (e.g., Latin American countries, other collectivist societies). By empirically examining attitudes and behaviors toward advertisements that depict (in)consistency in cultural values, marketers will be better able to evaluate *how* such cultural differences affect consumer behavior.

Vertical Integration and Profitability

Stephen Schmidt

Japan has been getting much recognition in recent years for its great economic successes There is theory which suggests that vertical integration, which is witnessed when a company is involved in all steps of the production process, could be the reason for this success This paper examines the effect of vertical integration on profitability for a sample of forty-five United States manufacturing and retail companies Many theories support the idea that vertical integration will have a positive effect on the profitability of a firm. But, there are other factors, such as increased transactions costs and diseconomies of scope, which could outweigh the positive aspects of integration I created a variable which quantifies the degree of vertical integration for each company (TOTAL). After running a least-squares regression, TOTAL was found to hold no significant effect on an American company's profitability This paper discusses in length the structures and laws of the economic structures of the United States and Japan, in order to explain the result

INTRODUCTION

In the early 1980's, the entire world looked towards Japan for what seemed like its great new innovations in the manufacturing process What the international business community slowly discovered was that this was not a new process, but a tradition of production which had come to fruition for the Japanese This "Japanese Miracle", as it has been often called, is based around a system called the *Keiretsu* In Japan, there are "Six Big *Keiretsu*", and it is these six big groups which control the entire manufacturing processes for the nation The purpose of a *Keiretsu* is to have the ability to unite companies at different stages of a single production process through the financing and support of large banks Many have wondered if it is this complete verticality which allows the Japanese firms to be so profitable in comparison to other countries. While the U S does not have a *Keiretsu*-like structure, due to different cultures and legal policies, the question that this paper sets out to answer is whether highly integrated US firms have a profit advantage over less integrated firms

THEORY

The reasons behind a desire to vertically integrate a firm can be separated into two different categories, those that are legal in the US and those which are not On the "legal" side, the first and most obvious advantage to integrating is the technical cost savings involved Often, it is better for a company to be involved in all parts of the production process, due to the economies of scale realized, rather than to let another company create the inputs This leads into the other advantage of vertical integration, transfer pricing. Transfer pricing, which is the price at which a firm transfers an input from "one division of a vertically integrated firm to another" (Shughart, 1996, p. 495), is often a very big factor in the cost of the final product A firm needs to determine if it is able to make this price a reasonable one for the firm, or if it is optimal to "farm out" the production of the product Since the goal of most firms is profit maximization, the outcome must be that the price of the subcontracted product is lower than the marginal cost for the parent company to produce the product in-house Many economists feel that having that ability to have control over each step of the production process is an obvious way to save money The term which best describes this argument is economies of scope These are the economies, or diseconomies which are realized when a firm vertically integrates For some companies, the benefits derived from vertical integration will far outweigh the costs, and that is a case in which the firm is experiencing economies of scope. If so, a vertically integrated firm will be more profitable.

Other reason for vertical integration would be defined as illegal by American courts. A company which has some market power will tend to use vertical integration as a way to get a stronger handle on the market. Through such anti-competitive methods such as foreclosure (squeezing competitors out of the market), price discrimination, and creation of barriers to entry, monopolies can drastically increase the amount of power that they wield in an industry. Though these types of strategies are restricted in the US through anti-competitive monopoly laws, Japan, for its' own reasons, allows such anti-competitive behavior.

How is it possible to find out the effect of vertical integration on profitability? The measure used in this study is TOTAL, which is a variable which is a percentage figure. For example, If a firm had one subsidiary, which gave 75% of its outputs into the parent company as an input, the TOTAL variable for this company would be .75. Why would the percentage of subsidiaries involved in supplying vital inputs be a good measure of vertical integration? First outlining the past attempts that have been made to quantify vertical integration would be helpful. One of the first things that comes to mind when thinking of a possible measure of vertical integration is the ratio of value added to sales. If the ration of value added to sales to high, then that would indicate a high degree of vertical integration. The main problem with using this device is that "it gives misleading comparison when firms or industries are located at varying stages in the stream of economics activity." (Shughart, p. 100). The reason for this is that all things equal, the closer the raw materials are to the end of the production stream, the higher the value added to sales ratio would tend to be. But many economists, in order to find the changes over time in the intensity of integration, have just accepted this limitation.

Livery and Porter introduce another way to measure vertical integration. Their goal was to find the historical increases in vertical integration, and using data which indicated whether the largest manufacturing firms moved into the upstream or downstream production process over the six year time period that they choose. They found that the most important moves towards integration were found in the early parts of the century. Although this measure was not used in a way which would relate to the regression used in this paper's study, it could be. The limitations stem from the inability to determine how widespread the company's involvement in non-manufacturing stages was. An example of this downfall would be a firm like McDonalds, where it could be seen as very integrated into the retail stage, but most of those retail stores are owned and operated by franchisers. Below this study will address the final decisions made in the creation of the TOTAL variable.

DATA

This study uses cross-sectional data, rather than to concentrate on one particular industry. It has been observed by many economists that some industries, such as oil and steel, have an obvious need to vertically integrate. While addition research into this topic could be interesting, a more interesting data set was possible in a cross sectional study. Therefore, the companies included in this data set were taken from a cross-section of the manufacturing industries. Although vertical integration may have an effect on the excluded division, this effect would not be as clear as in the manufacturing division, where an actual physical product was the outcome.

To procure this information, Dunn and Bradstreet's Book of America's Corporate Families was used. This is a book which lists the parent companies, their subsidiaries, and the industries in which they are involved. Also, for the second step of the data-gathering process, the 1978 Benchmark Input-output Accounts Table was used. These tables measure the amount that each separate Standard Industry Classification (SIC) codes inputs into the parent company. Using these sources, and working from a base of one hundred parent companies, the number of subsidiaries and the different SIC industries that each subsidiary was involved in was noted. The reason for obtaining the above data was by determining what SIC codes that the subsidiaries were in, it would then be possible to see if that line of work was an input into the parent company's business. By using the 1987 Input-Output tables, after converting the SIC coded into the coding system the tables used, it was possible to see whether or not the subsidiaries did in fact contribute to the parent company's main business. After determining this, the degree of vertical integration was determined by figuring out the percent of subsidiaries whose output was directly an input into the parent company.

Instead of approaching the measurement of vertical integration by any of the ways outlined in the theory section, the problems that previous economists were eliminated using the methods described below. This study used the percentage of outputs which the subsidiaries were a direct input into the parent company as the final measure. A quick example would be a soda company. The parent company could be involved in the development and production of the actual soda, and the subsidiaries of the parent company would be providing inputs such as the cans they are stored in or the transportation of the final product to market. By using the SIC codes of the parent companies and their subsidiaries, this study was able, through the use of the Input-Output tables to get a stronger measure of vertical integration.

The TOTAL variable was calculated by determining the number of possible combinations of the subsidiaries and the possibility of their outputs becoming an input into the parent company. This approach to explaining the degree of vertical integration experienced by a company is superior to the other previously mentioned methods for many reasons. The ratio of value added-to-sales method is faulty because this is a number which changes from industry to industry. For example, most manufacturing firms add a very large amount of value to the inputs that come into a plant, whereas a retail store may add a small amount, if any. But, that retail company could be vertically integrated with its distribution network, and in other areas which do not have any obvious value, but has the potential to increase profitability. Livery and Porter based their study on historic trends, which is limiting. To make projections about the future using past data is always risky. By taking each company and discovering the exact level of inputs that the subsidiaries have into the parent company, most of the difficulties encountered in the previous methods have been addressed. Also included in the data was such information as Return on Equity, Sales, Beta, Debt to Capital Ratio, and Dividend Payout Ratio. This data was combined with the vertical integration measures to compile the data set used for this study's regressions.

METHODS

To determine the effect of vertical integration on profitability, the regression form of analysis was used. By using this method, the effect of the independent variables (SALES, TOTAL, BETA, DIVISION and DIVIDEND), can be seen on the dependent variable, Return on Equity. The most basic regression run was:

$$\text{ROE} = B_0 + B_1 * \text{BETA} + B_2 * \text{DIVIDEND} + B_3 * \text{TOTAL} + B_4 * \text{DIVISION} + B_5 * \text{SALES} \qquad (1)$$

Table One: Regression Variables

VARIABLES	
ROE (Return on Equity)	It is a measure of rate of return on investment, more specifically, the investment contributed by shareholders
SALES	It is expected that as a firms increases sales, the profitability would go up, therefore creating a positive coefficient
TOTAL	This variable measures the total degree of vertical integration of all of the parent companies subsidiaries.
BETA	Beta is a recognized measure of risk. Since the data is cross sectional, it was necessary to control for the differing risks inherent in each industry represented, It is recognized in the financial field that when a shareholder takes on more risk, it expects to receive a higher reward.
DIVISION	This variable is a dummy for the division each company was in.
DIVIDEND	Although it is rather hard to represent the management techniques, these can sometimes be observed through the dividend payout ratio

RESULTS AND SIGNIFICANCE

These regressions show that none of the variables used in the regression except for BETA turn out be have any significant effect on profitability.

Table Two shows the results of the regression. In this table, the independent variable are listed vertically and the dependent variable of each regression horizontally.

Table Two: Regression Results

	Regression 1 ROE	Regression 2 ROE
Constant	-8.107 (-0.767)	-14.228 (-.2137)
BETA	1.59 (.676)	33.3168 (2.2873)**
DIVIDEND	.000 (0.0736)	
TOTAL	0.069 (0.5639)	-0.1052 (-0.1368)
DIVISION	1.0288 (1.057)	5.7575 (0.9586)
SALES	-0.308 (-1.744)	
DEBTEQUITY		0.0098 (0.1728)

The t-statistics (the variable coefficient divided by the standard error) is shown in parentheses
** denotes variables that are statistically significant at the 5% level

Something to note from this outcome is that the results are not as surprising as one would originally think. There is theory, as indicated before, that suggests the results could be significant, but there is other theory such as the cost of integration theory which indicates that there also might not be any correlation between vertical integration and profitability. There are many reasons that can be held accountable for this. First we must remember the main reason that it is assumed that American firms would be more profitable if they had a higher degree of vertical integration; because it has been observed that Japan, with its high degree of vertical integration has recognized large profits in the last ten years. This could be considered an indication of a system that had finally come together, and therefore something which American companies should consider. Also, the size of the data set and the possibility that the data set did not fully capture the effect of integration are also factors to consider when looking at the insignificance of the results.

KEIRETSU VS VERTICAL INTEGRATION

The technical aspects of the regression are not the only reasons that we may not have found the significance which was expected. Much of the theory in this paper was based upon the assumption that if it works in Japan, why can't it work here? By explaining the structure of Keirestu, some of the major differences in the two countries structure will come to light. This differences are at times major ones, and may explain to a large degree the lack of significance.

Japan has a history of a "centralized and hierarchical government orchestrating the actions of a centralized and hierarchical business sector." (Shughart, p. 63), whereas in he United States, we as a country have seen the welfare losses due to monopolies and acted against them. When the Japanese economy was destroyed after WWII, instead of looking towards smaller, family owned firms to rebuild the economy from the base up, the government came in a directed change. One thing that should be highlighted, is that the government was making these moves at the exact time that the Japanese anti-monopoly laws were put into effect. This shows the obvious lack of support that the government had had for these American imposed laws.

The U.S, by contrast, has seen the damage that the large monopolies can have on not only consumer welfare, but on the freedom and democracy the Americans trust and believe. As the large conglomerates took control over the economy, they also took control over the government, and the public felt as thought they were losing control. The laws that were put into effect were strongly supported by the public, and that is a reason for the difference between the two countries policies.

CONCLUSION

The results of this paper show no relation between vertical integration and profitability for United States manufacturing firms. This suggests that the costs of vertical integration are as great as the benefits in the United States. The steel industry has obvious cost advantages through vertical integration, but a manufacturing firm as the automobile industry may have increased overhead or the increased management costs that make vertical integration unprofitable. While it is true that many firms will see economies of scale, where a larger firm or plant is better, it is the economies of scope argument, which addresses the costs of integration, makes the advantages of integration not universal.

As stated before, this does make some sense. If there was a structure to the economy which guaranteed greater profits, it would seem that the country would have adopted it already. Instead the US has a variety of different forms of economy, ranging from monopoly to small cottage industry.

Japan in contrast has found great success in an extreme form of vertical integration. In Japan, there appears to be some relationship between vertical integration and profitability. In the US there are laws against many of the strategies that a firm would use in its justification of vertically integrating. American anti-trust law forbids foreclosure, price discrimination and entry barriers as "unfair methods of competition in or affecting commerce."(Shughart, p. 43) So, it is possible that the opportunity for the advantages to be realized in the US are fewer than in Japan, where such laws are overlooked in the interest of economic growth.

NAFTA and Jobs in the United States

Kristina Carrico

Faculty Advisor:

Dr. Rutilio Martinez

This research project was an investigation of the North American Free Trade Agreement's (NAFTA's) effects on United State's and Mexico's employment trends. The analyzation of government, public, and private citizen organizations' opinions concerning job losses attributed to NAFTA showed that jobs lost through Corporate America's investment in Mexico have not harmed the overall economy of the United States. The Mexican economy, however, has been negatively affected. An examination of the causes of job losses and long–run perspectives also pointed to the idea that the jobs lost attributed to NAFTA are significantly lower in the United States and higher in Mexico than commonly reported. Based on the sources evaluated, NAFTA will most likely cause the United States to become more efficient and increase employment in capital–intensive industries while improving Mexico's economy in the long-run even though there are severe problems in Mexico's current labor conditions.

HYPOTHESIS

The hypothesis this research study attempted to investigate was: Jobs lost in the United States through Corporate America's investment in Mexico through NAFTA do not harm the overall economy of the United States.

METHODOLOGY

A textual analysis of Government documents, books, journals, and Internet publications was employed to address the hypothesis. This study focused on opinions of well–known opponents of the North American Free Trade Agreement and on basic economic principles.

ASSERTIONS OF SOURCES EVALUATED

Author/Organization	1995 Total Job Losses from NAFTA	Description of Arguments
*1 Ross Perot, United We Stand America	300,000+	Low wages cause jobs to move to Mexico and Mexico has no market for US goods
*2 Marcy Kaptor, Byron Dorgan House and Senate	300,000+	The trade deficit will cause Americans to lose jobs
*3 Peter Cooper, Citizens Trade Campaign	470,000-638,000	US Government has not calculated satisfactory estimates

*1 United We Stand America, Inc. "NAFTA Impact Update."
*2 United States Congress. H.R. 2651 and S. 1417.
*3 Cooper, Peter. "Free Trade Reality Check."

ANALYSIS

United We Stand America (UWSA) is an organization that Ross Perot established to inform America of the dangers of NAFTA before it passed in Congress in January of 1994. The issue of jobs is extremely important for almost every American that is of voting age. It is possible that Perot used this as a tool to further his personal interests and to possibly win the presidential election of 1994 as well as attempting to protect the

American people from what he thinks will be a disaster caused by the North American Free Trade Agreement.

In his campaign against NAFTA, Perot asserts that NAFTA will not create jobs in America but it will in fact eliminate jobs by moving them to Mexico. Perot believes this for two main reasons: Firstly, Perot asserts that Corporate America wants to increase profits by paying lower wages to Mexican workers than to American workers. Secondly, he thinks that there will not be a market for American firms in Mexico because Mexicans cannot afford to purchase American goods (Perot, Choate 69). Perot notes the population differences between Mexico and the United States and compares the ability of people in each country to purchase goods. From these observations, Perot determines that the market of over 92,202,000 people in Mexico is not sufficient enough to create jobs in the future for the United States, the United States will lose jobs because of the low costs of labor in Mexico, and that NAFTA has a negative impact on the economy of the United States. When nations and economic factors are involved, the global economy becomes significant.

Perot does not consider the issue of the United States, European countries, and Japan being involved in international labor competition in his analysis of NAFTA. The debate that preceded NAFTA made it appear that this treaty was going to be the cause of the exodus of jobs to Mexico. However, it is conceivable that high wages in the United States are what cause low-skill manufacturing jobs to move to Mexico, not NAFTA. This is something that critics fail, consistently, to see. The benefits of sending jobs to Mexico (because of NAFTA) rather than to Singapore or Malaysia are the geographical proximity and the greater likelihood of Mexican workers to buy American products than workers from any other developing country.

Further, a look at history shows that low-skill manufacturing jobs had started to move south long before NAFTA was under discussion. The Maquiladora Program began in 1965 creating several hundred jobs in Mexico. Accordingly, the Program had grown to nearly 430,000 workers by 1988 (Vargas 1).

Perot's number of over 300,000 lost jobs resulting from NAFTA seems to come from the addition of numbers reported by citizens. The 300,000 plus number should "check" with the number of jobs created in the maquiladora industry. Considering the number of jobs created in Mexico and the idea that for every job created in Mexico a job is lost in the United States, the actual number of job displacements is far fewer than it is commonly reported. By using the number of jobs created in Mexico before NAFTA was implemented, it is possible to estimate how many jobs have been lost in the United States and sent to Mexico.

A recent publication by CIEMEX-WEFA, a private organization that measures activity of the maquiladoras in Mexico, recorded that 546,588 workers were employed in December of 1993. By October of 1995, the number had grown to 689,420 employees (1). This is a change of only 142,832 workers in nearly two years. Representative Kaptur and Senator Dorgan also estimate over 300,000 jobs lost in the United States in November of 1995, inferring that over 157,168 workers were hired by multi-national firms in Mexico in the month of November, 1995.

To calculate the number of jobs gained in Mexican maquiladoras, first take into account that the historical rate of growth in the maquiladora industry is estimated at 18 percent per year (it was 19.7 percent from 1983-1988, and 17.7 percent from 1989 to 1993 with projections for greater consolidation later in the 1990's) (Vargas 1-2). Then 546,588 workers at the beginning of 1994 increased by 18 percent equals 644,974 workers employed in December, 1994. Then 644,974 workers increased by 18 percent equals 761,069 workers by December, 1995. By subtracting the number of workers in December, 1993 from the number of workers in December, 1995, only 214,481 employees remain, leaving less than 215,000 workers in the United States displaced.

This number is, however, an overstatement of the number of jobs that have moved south from January 1994 to December 1995. Adjust the number of jobs created in the maquiladoras for 1994 and 1995, (214,481) to account for the close to 20 percent investment in the maquiladora industry from non-American firms, i.e., European and Japanese firms that moved jobs to Mexico from places other that the United States. The equation 214,481(.8)=171,585 workers, thus shows that the actual number of workers who were displaced in the United States is about 170,000.

Also, by simply adjusting CIEMEX– WEFA's data for the number of workers employed in maquiladoras from December, 1993 to October, 1995 for the 20 percent non–American investment, the equation 142,832(.8) yields 114,266 displaced American workers. Thus actual job losses from NAFTA are from under 115,000 to slightly over 170,000.

According to the NAFTA Office, the process of shifting America's labor–intensive jobs to capital–intensive jobs will "raise incomes and improve the mix of jobs in the economy" in the United States (1). Kelly George and Lori Taylor, economists from the Federal Reserve Bank of Dallas, Texas, attribute the recent growth in high–tech manufacturing in Texas to the increase of Mexican demand and the increase of exporting firms that have relocated to Texas to take advantage of their location at the border. George and Taylor have seen that "Texas has been a major beneficiary of Mexico's trade liberation" because "as employment patterns shift in response to trade, workers can move geographically, as well as occupationally" (22).

Ohio has also seen this shifting occur in its automobile manufacturing industry, however jobs have shifted out of instead of into Ohio. Steven J. Davis of the University of Chicago believes that it is normal to see dislocation in capitalistic economies. He writes, "The phenomenon of large–scale job destruction and creation has been part and parcel of the U.S. economy and other market economies for as long as we have [had] data" (Davis qtd. in Norton 55). Perot's concern with "large–scale job destruction" is that workers have lost their jobs and will not be able to find employment in the future. This will cause the lifestyles of Americans to deteriorate and negatively affect the overall economy of the United States. Although it is difficult to find new jobs, there is assistance available through Unemployment Insurance, the Economic Dislocation and Worker Adjustment Assistance Program, and the Trade Adjustment Assistance Program. These programs allocate temporary income and retraining services to workers who apply and are qualified to receive assistance.

To address Perot's second assertion that Mexico does not provide an adequate market for American goods one must consider Mexico's purchasing history. Since 1988 Mexico has been the third greatest importer of American goods. Exports to Mexico from 1994 to 1995 also show that Mexico, a poor country, is still the third most important customer of the United States (Current Business Survey 70). Further, in per capita terms, Mexicans buy more from the United States than the Japanese. Before NAFTA, Mexico was already an important customer of the United States. Hence, after NAFTA has had time to help transform the Mexican economy, Mexico is likely to become an even more valuable customer of the United States.

One of the greatest concerns of Representative Kaptur and Senator Dorgan is the trade deficit between the United States and Mexico. According to H.R. 2651 and S. 1417, Mexico is supporting its peso with $30 billion in loans from the United States. H.R. 2651 and S. 1417 also point to the devaluation of the peso and how it has "offset tariff reductions and other trade benefits the United States expected to achieve from the agreement" (H.R. 2651 section 2 paragraph 2). Representative Kaptur and Senator Dorgan are referring to the after affects of the "peso crisis."

With time, Mexico will improve its economy. Mexico, in 1992, created a voluntary labor union called the National Accord for Raising Productivity and Quality that "reflects the growing preoccupation of government, employers and belatedly, organized labor with addressing changes needed in a still largely corporatist labor– management relations system (Mexico Labor Trends 1991–1992). With time comes new leaders and with new leaders comes new changes. Time is the key to what Mexico's economy will be with the results from foreign pressure. Major structural changes have already taken place in Mexico's economy. For instance, the reduction of subsidies to inefficient industries, liberalization of laws that regulate foreign direct investment, rising environmental conscience, and other reforms have been undertaken in Mexico.

Representative Kaptur and Senator Dorgan's concern for the United States to eliminate the trade deficit and to lessen its ability to cause Americans to lose jobs is also a matter of time. The trade deficit according to H.R. 2651 and S. 1417 at the end of 1995, is $30 billion. The concept suggested by Kaptur and Dorgan is that if the United States purchases more goods from Mexico, fewer goods will be purchased in the United States and this will cause Americans to lose jobs. Therefore, the trade deficit is presumed to cause Americans to lose jobs. However this is not the case.

The problems with this argument are that a very large percentage of Mexico's exports to the United States are manufactured goods which are produced in plants that are only part of the production processes of American multinational corporations (Vargas 3). The trade deficit results partially from many maquiladoras that ship goods assembled in Mexico with parts from the United States back to the United States. Also various goods purchased from Mexico are not produced in the United States. Among these are handcrafts and oil and other labor-intensive products. Importing goods from Mexico that are not produced in the United States does not cause Americans to lose jobs. This contributes to the trade deficit and therefore does not cause significant job losses in the United States.

Peter Cooper from Citizens Trade Campaign joins Ross Perot, Marcy Kaptur, and Byron Dorgan in his anti-NAFTA position in his article, "Free Trade Reality Check." Cooper alleges that the Government's main NAFTA economist from the Institute for International Economics, Gary Hufbauer, is mistaken about his findings for net job loss due to NAFTA. Cooper asserts that Hufbauer's argument that there is virtual "full employment in the U.S." and that "there can be no net job loss in the economy due to trade with Mexico" is not correct because "plugging the real life U.S. Department of Commerce data on NAFTA trade flows...shows a net U.S. job loss of over 600,000 in 1995 (2)." Cooper believes that this formula is not reliable and should not be taken seriously.

After examining this issue, it became apparent that there is no formula that adequately counts the number of job losses to NAFTA. Thea M. Lee, in a Senate hearing on May 27, 1993, agrees that the Hufbauer and Schott analysis relies on incomplete methodology and makes assumptions that are not appropriate to calculate the total number of job losses or gains from NAFTA (27). The process of developing an equation that includes every industry, every firm, and every detail that is significant in the American economy to yield the exact number of jobs lost because of NAFTA is extremely difficult and cumbersome.

Cooper exposes the inadequacies of the American Government's multipliers and assumptions and proposes that their predictions are not accurate enough to be considered valid. He then leads us to the idea that we must rely on other factors to provide more accuracy to assess the impact of NAFTA on American jobs. Thus, balancing the assumptions with the number of jobs created in Mexico, noting the likelihood that Mexico will develop into a powerful consumer market for American goods, and witnessing the creation of jobs in the United States because of NAFTA would provide more accuracy in determining the number of jobs affected by NAFTA.

With more labor-intensive investment in Mexico, Corporate America's activity will create more productive opportunities for firms in the United States. As Mexico privatizes its sea ports, airports, railroads, and some petrochemicals, foreign direct investment will increase and the consumer market will also expand. When the market expands, more capital-intensive jobs will be created in the United States to supply the increased demand for American goods in Mexico and jobs in the United States will continue to shift. Jobs will shift to capital-intensive industries that have a comparative advantage over Mexico and there will not be mass unemployment in industries were Mexico has a comparative advantage in labor-intensive industries. It has even been suggested that, when the "Baby Boomers" retire, border controls will be loosened to allow Mexican workers to come and work in the United States (Wescott 23 May 1996).

CONCLUSION

The North American Free Trade Agreement is promoting economic integration and trade with Mexico and is forcing changes in the occupations of many Americans. Although the number of job displacements are uncertain, the overall effect of NAFTA on jobs and workers in the United States has been minimal. For reference to the previous calculations, the January, 1996 issue of Employment and Earnings states that the total number of employed workers as of December, 1995, was 114,373,000 (U.S. Dept. of Labor p. 152). As of April, 1996, the number of workers in America was 123,600,000 (Colorado Labor Force Review 2). With job losses from 115,000 to 170,000 and numerous jobs created by NAFTA, it is proven that a minuscule percentage of jobs have been lost in the United States because of NAFTA. The number of jobs lost is lower than commonly reported and does not harm the overall economy of the United States.

Gender Differences in Investment Expectations

Teresa D. Harrison
Rosemary T. Cunningham
Department of Economics
Agnes Scott College
141 East College Avenue
Decatur, GA 30030

Faculty Advisor: Rosemary T. Cunningham

There has been a great deal of focus on women investors and as a result brokerage firms are beginning to market their services directly to women. Yet, there has been little evidence of a difference between men and women and their investment behavior or expectations. This paper investigates the existence of gender differences by presenting the results from a survey distributed to more than 500 students taking introductory economics at 10 colleges and universities. In particular, the results indicate that women differ from men in the way in which they (1) rate their understanding of the financial markets, (2) characterize their risk preferences, (3) select the most important resource for investment advice, and (4) estimate the Dow Jones Industrial Average.

INTRODUCTION

Recently there has been some attention by the media and brokerage houses concerning how men and women differ as investors. In particular, there is some concern that women may be reluctant to participate in more risky investment assets and therefore may miss out on the higher returns these assets may generate. Given the focus on the ability of the Social Security system to handle the upcoming retirement of the baby-boomers and recent proposals for privatizing the system, this issue takes on even greater importance. Since women on average earn less than men, their ability to prepare for retirement with contributions to Social Security, other pension plans, and financial assets in general is more limited. Together with the longer life expectancy of women, this may portend a much reduced standard of living for women in comparison to men in the later years (Bajtelsmit and Bernasek, 1996). To compensate for this disadvantage, will women be willing to take on more risk in order to increase the magnitude of their returns?

It has been repeatedly noted from U.S. Census data that income for men and women retirees differs substantially. In 1992, the median income for elderly men was $14,548, whereas for women, median income was $8,189 (U.S. Census Bureau, 1995). This disparity seems certain to continue given the current wage gap between males and females. The Department of Commerce reports that in 1995, median income for year-round, full-time workers was almost $9,000 greater for men than women.

Recent studies by Jianakoplos and Bernasek (1996) and Bajtelsmit, Bernasek, and Jianakoplos (1996) investigate gender differences in investment behavior using the 1989 Survey of Consumer Finances as the source of data on risky asset holdings for individuals. In "Are Women More Risk Averse?" Jianakoplos and Bernasek examine household holdings of risky assets in

620

portfolios to determine whether financial decision making reflects differences between men and women. They find that single women are relatively more risk averse than single men or married couples. Bajtelsmit, Bernasek, and Jianakoplos investigated gender differences in allocating wealth to defined-contribution pensions and found that women are also more conservative in their allocations to pensions implying less financial security for women upon retirement. These studies by Bajtelsmit, Bernasek and Jianakoplos indicate that women follow an investment strategy that on average will produce lower returns and will cause elderly women to be at even a greater income disparity with elderly males. Given the results of this research, our study attempts to determine if a more conservative investment strategy will continue with the next generation.

This project attempts to investigate gender differences in investment expectations among college students by asking students in introductory economics courses about their knowledge of financial markets and their willingness to take on risk. The results indicate that women perceive themselves as less knowledgeable in the market and less willing to take on risky investments. These results have astounding implications for the prosperity of elderly women in the future.

THE SURVEY

This survey involved 576 students taking introductory economics at 10 colleges and universities during the Fall 1996 semester. Of the 576 students, 270 (or 47 percent) were female and 306 (or 53 percent) were male. After collecting information on age, sex, citizenship, and family income, the survey asked the students about their experience with various saving and investment opportunities and to estimate the current value of the Dow Jones Industrial Average (DJIA). The survey then focused on the answers of female and male college students to the following questions:

- How would you rate your understanding of financial markets?
    - very knowledgeable.
    - somewhat knowledgeable.
    - not very knowledgeable.
    - do not understand financial markets at all.
- How would you characterize yourself?
    - willing to take on very risky investments.
    - somewhat willing to take on very risky investments.
    - not very willing to take on very risky investments.
    - wish to avoid risk completely.
- When looking for investment opportunities, what factor would you feel is most important?
    - recommendation by an investment advisor.
    - recommendation by a friend or relative.
    - personal knowledge of company or product.

RESULTS

The results of the survey indicate a statistically significant gender difference in the answers to the questions. In general, men are more willing to estimate the value of the DJIA (56.2 percent versus 28.2 percent for women), are more likely to be correct in estimating the DJIA (25.5 percent versus 11.5 percent), evaluate themselves as somewhat knowledgeable about investments (41.8 percent versus 27.8 percent), and characterize themselves as being somewhat willing to take on very risky investments (47.4 percent versus 28.5 percent). Similarly, women are more likely to respond that they do not understand financial markets at all (12.6 percent versus 4.9 percent for men), characterize themselves as not very willing to take on very risky investments (61.9 percent versus 42.5 percent), and respond that they wish to avoid risk completely (7.8 percent versus 3.3 percent). Finally, men and women differed in their responses about what factor was most important to them when looking for investment opportunities. Men were statistically more likely to respond that personal knowledge of a company or product was more important to them (61.4 percent versus 43.3 percent for women), while women were statistically more likely to respond that a recommendation by an investment advisor was more important (46.3 percent versus 34.3 percent for men) or recommendation by a friend or relative (10.7 percent versus 6.5 percent). The only response to which there was not a significant gender difference was for students responding that they were very knowledgeable about financial markets. Table 1 summarizes the responses to the survey.

Table 1: Survey Response (Sample: All Students)

	Male Students	Female Students	T-Statistic
Percent Responding to DJIA	56.21	28.15	-7.11
Percent Responding Correctly to DJIA	25.49	11.48	-4.43
Percent Responding to Recommendation by an Investment Advisor	34.31	46.30	2.94
Percent Responding to Recommendation by a Friend or Relative	6.54	10.74	1.78
Percent Responding Personal Knowledge of Company or Product	61.44	43.33	-3.29
Percent Responding Very Knowledgeable	1.96	0.74	-1.28
Percent Responding Somewhat Knowledgeable	41.83	27.78	-3.58
Percent Responding Not Very Knowledgeable	49.67	58.15	2.04
Percent Responding Do Not Understand Financial Markets at All	4.90	12.59	3.24
Percent Characterizing Themselves as Willing to Take on Very Risky Investments	4.90	0.37	-3.51
Percent Characterizing Themselves as Somewhat Willing to Take on Very Risky Investments	47.39	28.52	-4.75
Percent Characterizing Themselves as Not Very Willing to Take on Very Risky Investments	42.48	61.85	4.73
Percent Responding Wish to Avoid Risk Completely	3.27	7.78	2.34

To see whether gender differences persist for subsets of the sample, the analysis narrowed to students who responded that they were either very or somewhat knowledgeable about financial markets and who were able to estimate the Dow Jones Industrial Average within 1000 point band. Of the 211 students who responded that they were either very or somewhat knowledgeable about financial markets, there remained a statistically significant difference between male respondents and female respondents of answering the DJIA (67.9 percent for men versus 33.8 percent for women), answering the DJIA correctly (36.6 percent versus 14.3 percent), and willingness to take on very risky investments (8.2 percent versus 0.0 percent). Those results are reported in Table 2.

Table 2: Survey Responses (Sample: Students Responding Very or Somewhat Knowledgeable about Financial Markets)

	Male Students	Female Students	T-Statistic
Percent Responding to DJIA	67.91	33.77	-5.07
Percent Responding Correctly to DJIA	36.57	14.29	-3.85
Percent Characterizing Themselves as Somewhat Willing to Take on Very Risky Investments	8.21	0.00	-3.45

Of the 109 students who were able to estimate the Dow Jones Industrial Average within 1000 point band, there remained a significant statistical gender difference in men characterizing themselves as willing to take on very risky investments (8.9 percent versus 0.0 percent for women), as well as rating their understanding of financial markets as very knowledgeable (6.4 percent versus 0.0 percent), somewhat knowledgeable (56.4 percent versus 35.5 percent), and not very knowledgeable (35.9 percent versus 61.3 percent). Table 3 summarizes those results.

Table 3. Survey Responses (Sample: Students Able to Estimate DJIA Correctly)

	Male Students	Female Students	T-Statistic
Percent Characterizing Themselves as Somewhat Willing to Take on Very Risky Investments	8.97	0.00	-2.76
Percent Responding Very Knowledgeable	6.41	0.00	-2.30
Percent Responding Somewhat Knowledgeable	56.41	35.48	-2.01
Percent Responding Not Very Knowledgeable	35.90	61.29	2.46

CONCLUSION

The survey results show that women are continuing a conservative attitude toward investing which implies low returns on investment strategies for these women in the future. Through this survey, we also discovered that college-aged women are more hesitant to claim knowledge of financial markets or to respond to questions about the Dow Jones Industrial Average. In the survey question that asked participants to estimate the Dow Jones Industrial Average, participants had nothing to lose by taking a guess. Yet, only 28 percent of the female participants wanted to take that chance versus 56 percent of males. Does this lack of confidence in financial markets stem from an actual difference in financial education for men and women or from social behavior differences in which men assume the risk of being more assertive? The answer to this question is more difficult to ascertain, but nonetheless, needs to be studied more heavily, especially given the increasing attention of privatization of pension plans. By determining why investment differences occur, strides toward improving women's participation and success in financial markets can be made which will hopefully lead to greater income equality in the future.

Do Dollars Make a Difference? The Relationship Between Expenditures and Test Scores in Pennsylvania's Public Schools

Jonathan M. Klick

Department of Economics
Villanova University
Villanova, PA 19085

Faculty Advisor:

Charles Zech

This paper examines standardized test scores from effectively every public school in the state of Pennsylvania to determine what relationship exists between per pupil expenditures and student achievement. The results of this study show that expenditures have virtually no effect on achievement, while the socio-economic backgrounds of a school's students consistently and significantly affect achievement.

INTRODUCTION

In 1983, the National Commission on Excellence in Education released its report "A Nation at Risk." In this report, the commission confirmed what other studies had been indicating for years: U.S. school children were lagging behind students in other industrialized countries in the basic fields of science and mathematics (Burtless, 1996). Also, many people started to believe that contemporary school children were learning less in basic subjects than those of just a generation ago. This seemed to be supported by declining scores on the Scholastic Aptitude Test (SAT) and other similar standardized tests.

This realization of declining educational achievement spurred the implementation of school improvement programs across the country. Most of these programs called for an increase in the amount of funding provided for schools. Implicitly, this holds that expenditures, at least partially, determine the quality of an education system as measured by quantified indicators of student knowledge of basic subjects.

Intuitively, this assumption makes sense. With more money, schools can "buy" more education. Presumably, more funding will allow school districts to hire better teachers, purchase higher quality text books and employ any number of other tactics which should give schools the ability to do their job.

However, it appears as though intuition was wrong in this respect. Before "A Nation at Risk" was published the trend did not lend credence to the assumption that more money leads to better test scores. The period of declining test scores, from the early 1960s through the early 1980s, coincided with a period when expenditures on education were rising in real terms. Per pupil expenditures rose 58 percent in real terms during the 1960s and 27 percent in the 1970s (Sowell, 1993). During the decade after the report, expenditures rose 29 percent, but there was little appreciable improvement. In the 1990s, American 13-year-olds finished last in a test comparing their science and math skills with students from five foreign countries and four Canadian provinces (Will, 1994), and SAT scores had not begun any recovery to the early 1960s level.

Management expert Russ Ackoff has commented that such testing measures are misleading in that cross-generational comparisons are impossible. He has made the point that today's students learn things that would have been impossible for those of a generation ago to learn (Ackoff, 1996). While a comparison of specialized knowledge does seem unfair, there are still grounds to compare the skill levels each generation exhibited in rudimentary subjects such as reading and math. It is doubtful that there have been the cutting-edge knowledge explosions in vocabulary or arithmetic necessary to turn the comparison into one of apples and oranges. And one need not go back to previous generations to witness a decline in these basic skill areas. The National Assessment of Educational Progress's final 1994 Reading Report Card found that there was a significant decline in the proportion of twelfth graders at or above a proficient reading level since 1992 and a significant decline in the proportion of twelfth graders at or above the basic level of reading (Hirni, 1996).

However, even if comparisons, cross-generational and international, are abandoned altogether, there are still practical evaluations of the quality of education that can be made. American Telephone has reported that, on average, 115 out of 117 applicants flunk its employment exam and Motorola has found that 80 percent of its applicants fail its exam which evaluates English skills at the seventh grade level and math skills at the fifth grade level (Will, 1994).

The situation in Pennsylvania's public schools is perhaps worse than that of the nation as a whole. According to the Heritage Foundation, Pennsylvania's students perform worse on the SAT than all but students from six other states. David Hombeck, the superintendent of the Philadelphia school district, the state's largest, was quoted in The Philadelphia Inquirer as saying, "Fewer than 20 percent of our kids can read or do math or do science at what we consider a proficient level (Jones, 1996)." In terms of practical measures of school achievement, there are also indications that Pennsylvania's public schools are deficient. School board members from throughout Chester County, whose districts have consistently scored among the highest in the state on Pennsylvania's educational assessment tests, have testified that employers have often come to them with the complaint that their schools are turning out students who do not even have the skills requisite for entry-level employment (Klick, 1996).

Following the conventional wisdom, many educators have claimed that more funding is necessary to improve the quality of education in the state. In the School District of Philadelphia's plan for improving its schools, "Children Achieving," the ninth stated objective in the Executive Summary is to "Ensure adequate resources and use them effectively." In its explanation of this objective, the plan states "Adequate resources are a commonsense [sic] precondition to virtually all children achieving at high levels . . . additional resources are an absolute prerequisite for dramatically improving student outcomes." In 1994-95, Philadelphia spent $6,261.17 per pupil, just short of the $6,804 per pupil state average which places it higher than the state averages of all but six states.

Given the anecdotal and quantitative evidence that public schools are deficient in providing American students with fundamental skills and in preparing them for the work force, it is reasonable that parents, politicians and educators would want to remedy the system. This desire is obvious enough. However, the means to improvement are not quite so obvious. Conflicting results have been obtained by numerous studies of the relationship between per pupil expenditures and student achievement.

In a survey of studies analyzing the determinants of student performance, Eric Hanushek found that in only 34 percent of 377 studies on the subject were expenditures found to be statistically significant. And, of those where expenditures were found to be significant, 20 percent found that a negative relationship actually existed (Burtless, 1996). Therefore, only 27 percent of these tests found expenditures to have a significantly positive effect on student achievement.

Similarly, in its 1993 Report Card on American Education, the group Empower America, which counts among its leadership former Secretary of Education William Bennett, noted that of the 10 states that consistently rank among the top in various student achievement tests, only one rated in the top 10 in terms of per pupil spending (Wisconsin at No. 8).

This evidence is sufficient to call the assumption that money is the key to quality education into question. However, it is not sufficient to conclude that, because studies of a national scope propound there is no relationship, there is no linkage between expenditures and achievement in a specific geographic area. To do so would be to commit a fallacy of decomposition.

It is the purpose of this study to analyze specifically the schools in the state of Pennsylvania to determine whether or not expenditures play a role in student achievement. Knowledge of this relationship is necessary in order to formulate effective plans to improve the quality of education in the state.

THE MODEL

Beginning in 1992, the Pennsylvania Department of Education began administering the Pennsylvania System of School Assessment (PSSA) test. This test is taken by fifth, eighth and eleventh graders in February or March of every year, and it measures basic reading and math skills. The 1994-95 school year marked the first year every public school in the state participated in the testing.

BEST COPY AVAILABLE

Scores on this test were selected as the basis for the dependent variable in this study. This test is particularly well-suited to serve as a proxy for school achievement in that every student must participate in the testing. Unlike the SAT which is taken only by a self-selected group, the PSSA has the potential to measure achievement by all students, not just those who are college bound.

The PSSA is scored on a relative basis. That is, no absolute score is given in terms of percentage of questions answered correctly. Instead, results for schools are related on a basis of the percentage of a school's students whose scores fall within each quartile of the distribution of scores throughout the state. This relative grading provides yet another advantage of using the PSSA as the proxy for school achievement. By using relative scores, an analysis can be made of what determines differences among schools in educational quality.

In order to yield a quantified "score" for each school in this study, a weighting system was developed whereby scores in the fourth quartile received three points, scores in the third quartile received two points, scores in the second quartile received one point and scores in the first quartile received no points. Mathematically, this scoring scheme can be related as follows:

$$\text{Score} = (3 * \%\text{ of students in Q4}) + (2 * \%\text{ of students in Q3}) + (1 * \%\text{ of students in Q2})$$

Effectively, there were nine different analyses performed in this study. Scores on the reading section of the PSSA and scores on the math section of the PSSA were both studied as well as the summation of both. These analyses were carried out at the fifth, eighth and eleventh grade levels. These separate tests were done to examine any differences in the relationship that result from either grade level or subject matter.

The explanatory variables investigated in this study are total expenditures per pupil, percentage of student body coming from low income households, size of school district and occurrence of strikes within the district.

Total expenditures per pupil was measured by dividing total expenditures made by a district by the average daily attendance within that district. These data have been summed for the years 1989-1995. The rationale for this summation is provided by the assumption that education is cumulative; therefore, if expenditures do have an impact on education, it is more useful to look at expenditures over the educational career of a student rather than at expenditures made just in the year the test was taken. While there is a danger in that it is impossible to account for migration between school districts during this time period, it is not beyond reason to assume these changes will randomize out. Presumably, the relationship between expenditures and achievement will be positive.

Percentage of students from low income households (Poor) was chosen as an indication of the social capital available to students (Burtless, 1996). Presumably, poverty will limit the amount of leisure time a parent has to spend with a child in such activities as reading together or doing homework. Also, these data are likely to give an indication of the ability of a household to provide educational resources to a student such as books or computers. Intuitively, the relationship between this variable and achievement will be negative.

The size of a school district is measured by its average daily attendance (ADM). This variable was chosen to examine the effects of economies and diseconomies of scale on the education process. Intuitively, it seems as though there are certain efficiencies that can be gained in larger districts which can eliminate the duplication of administrative tasks, thus freeing more resources for educational purposes. However, on the other end of the spectrum, a district that is too large may not be able to manage its schools effectively and thus will become bureaucratized and wasteful (Sowell, 1993). It is reasonable to assume that ADM will exhibit a quadratic relationship to achievement with a positive relationship turning into a negative relationship after some optimal size is reached.

Lastly, occurrence of strike (strike) was included due to the presence of the claim by the department of education that some districts may not have been able to cover all of the topics tested by the PSSA due to teacher strikes in the districts. This is a fair enough consideration, and it warrants inclusion in the study. Strikes were measured as a dummy variable with one representing the occurrence of a strike in the district and zero denoting the absence of any strikes in the district during the year. Obviously, as noted by the department's concern, a strike is likely to have a negative effect on achievement.

COMMENT ON FINDINGS

Regarding expenditures, of the 63 different functional forms of the model that contained some expression of expenditures, 22 of those forms showed expenditures to be statistically insignificant at a 0.05 significance level. Of the 41 forms which showed expenditures to have a significant impact upon performance, 16 showed that impact to be negative. That is, when more money is spent per pupil, tests scores actually drop. For those forms which rendered a significantly positive coefficient with the expenditure term, that coefficient, in every case, was so small (generally about 0.000005) that an increase of $100,000 per pupil would be necessary to raise the school's score by 0.5 points. Obviously, this is an impractical scenario.

Of the 90 functional forms of the model that contained "poor" as an explanatory variable, poor's coefficient (generally about -3.0 for total scores) was significantly negative 90 times. As for the effect of a strike on student performance, in no case did strike's coefficient turn out to be statistically significant. Finally, no consistently significant relationship was found between ADM and achievement.

Also, it is interesting to note that the explanatory power of the regressions decreased significantly from the fifth grade scores to the eighth grade scores and again to the eleventh grade scores. The coefficients of determination for the fifth grade scores neared or surpassed 70 percent, while those for the eighth grade scores dropped under 60 percent and those for the eleventh grade scores fell between the 30 and 35 percent range. Even though each area of the study focuses on different groups of students, it is likely that this decline would have been observed in a longitudinal study as well.

One explanation for this observation may be what Chester Finn of Vanderbilt University calls the "9/91" problem. Finn notes that by the time a child reaches the age 18, only nine percent of his time has been spent in schools, while the other 91 percent often subverts what schools attempt to do (Will, 1994). This phenomenon can be applied to this situation because, presumably, the time children of fifth grade age or younger spend away from schools is spent primarily with families which serve an educative purpose as well. However, as children age, separation from families becomes more distinct and outside social influences play more of a role in the individual's development. Almost by definition, these outside influences will be more difficult to specify and nearly impossible to quantify. From this reasoning, it is obvious that the true relationships involving older individuals' achievement will include more of these unspecifiable influences than those of younger students. Therefore, the explanatory powers of a quantified relationship will decrease as age increases.

CONCLUSION

The most clear-cut finding of this study is that dollars definitely do make a difference. But that difference is not necessarily made in the schools; instead it is made in the home. Poverty in the home, without fail, proved to be a significant determinant of whether or not a student will succeed in school. The data could not possibly make this point more clearly. Those schools heavily populated by low income students are unable, on average, to educate those students in fundamental math or reading skills.

The reasons for this linkage are not clear. Perhaps these students come to school initially deficient from lack of significant parental attention in the pre-school years, or maybe these students do not have the proper support system needed to reinforce the skills taught in the schools. This could be the case for a myriad of reasons. Perhaps low income parents do not have the free time to spend with their children. Another possibility might be that poorer children do not have sufficient resources at home to allow for reinforcement of school lessons such as books and computers. One other possibility is that there may be a negative correlation between income and education of parents. This point is in fact made in some economic literature. This speculation would hold that affluent parents are better educated and are, therefore, better able to serve as a resource for their children as teachers in their own right. Perhaps this resource is not readily available to children from low income families.

However, regardless of the reason, family income does make a difference in student achievement. Such a conclusive statement cannot be made for school expenditures. Given this situation, it may be sensible for communities to divert funds from the schools and instead spend them in the community. By improving youth centers by employing educators and purchasing improved educational material, a significant resource may be provided for those students who cannot look to their homes for help. Another option might be to develop a

BEST COPY AVAILABLE

mentor program whereby poor youth can be put in contact with a role model who is available to help students achieve.

These options need to be researched because there is no proof that money spent on these programs will be any more effective than the money spent in schools. But, in light of this study, at least in Pennsylvania, an alternative to school spending, which has only, at most, a negligible effect, must be investigated.

The practical question that arises for the schools themselves is, why does money seemingly not make a difference in student achievement? The first possibility would hold that schools are operating in a position of zero marginal or negative marginal benefits of funding. Effectively, the schools are spending too much money.

This conclusion has been used by many affluent districts to fight the claims of poorer districts that the funding system for education (i.e. moneys coming from localized tax bases) creates separate and unequal school systems for the rich and poor. By explaining away this claim in saying that money does not matter but to continue to spend thousands of dollars more than poorer districts, the affluent communities contradict themselves. If money does not make a difference, are there not more productive uses for that tax revenue than just throwing it at the schools? If the conclusion could be made through research that there is a different relationship that exists for affluent and poor districts then there would be grounds for allowing the disparity to continue. In the absence of any such research, it seems reasonable to claim that if the marginal benefit of spending in schools is effectively zero then school expenditures could be reduced at every school without affecting achievement. Thus, a more efficient system is created. Perhaps this could lead to the conclusion that there should be a standard per pupil expenditure throughout the state.

A more plausible explanation would be that schools are not using the money they have effectively. This possibility has been raised by Stanford economist Thomas Sowell. Sowell has cited studies of the Milwaukee and New York City school systems which have shown that less than half of the money spent per high school student in New York or per elementary school student in Milwaukee actually reached the schools (Sowell, 1993). His explanation for this is the growing bureaucratization of the public school establishment. Because of this, funds get eaten up in non-instructional administrative costs.

Or perhaps the schools are using their funds effectively, but their objectives are not the education of students in basic subjects such as reading and math. During the period of declining test scores, there has been a proliferation of non-academic instruction involving courses in sex education, environmental awareness and other social causes that were not popular before the 1960s. This possibility is reasonable if that is what society values. Perhaps, as Ackoff claimed, today's students are learning more in a plurality of subjects. If this is the case, then maybe schools are using their funding effectively.

Currently, Pennsylvania's public schools are in the midst of reforms that claim to be geared toward improving deficiencies in basic subjects such as reading and math. These deficiencies are glaring in the light of standardized test scores and in the context of the complaints of employers that Pennsylvania's high school graduates are not prepared for employment in even entry-level positions. One of the main thrusts of most of these reforms involves dedicating more funding to education. This study should give pause to those reformers. Maybe after some structural changes are initiated in the schools, this added money will be productive, but as things stand now, it is likely that any extra money will not have an appreciable effect on helping students achieve.

ACKNOWLEDGMENTS

The author would like to express his appreciation to Ms. Rebecca Tice for her assistance with data entry.

The Income Distribution Effects of IMF Balance of Payments Stabilization Tools: A Case Study of Monterrey, Mexico

Charlotte Opal

P.O. Box 7505
Winston-Salem, NC 27109

Faculty Advisors: Perry Patterson, Michael Lawlor, and Dan Hammond

Abstract. A country can experience a currency crisis after a period of prolonged balance of payments deficits. The International Monetary Fund (IMF) encourages devaluing the domestic currency, reducing the government budget deficit, and slowing the growth of the money supply to stabilize the currency. The IMF examines the macroeconomic effects of these actions, but often ignores their effects on income distribution arising from changes in the inflation rate, rising unemployment, and reduction in benefits for the poor.

This paper presents an analytical framework which allows us to evaluate the social effects of each element of these IMF currency stabilization programs. It includes a discussion of previous literature linking stabilization policies and social outcomes and illustrates these outcomes using price, wage, and unemployment data the author collected in Monterrey, Mexico, including over 50 interviews with Mexican workers and economists. The author concludes that while the overall income distribution effects are difficult to measure, parts of the stabilization policy did appear to adversely affect the poor and were therefore regressive in terms of income distribution.

BACKGROUND TO THE ECONOMIC CRISIS IN MEXICO

The December 1994 peso crisis in Mexico was the culmination of a year of instability in Mexican financial markets. Beginning with the January 1st rebellion in Chiapas, confidence in Mexican markets dwindled as various political crises undermined stability in the country and the high current account deficit began to look unsustainable to foreign investors. The capital-flight pressures and current account balance deficit placed downward pressure on the value of the peso, as peso holders valued other currencies more, either to purchase goods with or to invest with. Foreign currency reserves fell from February to April 1994 as the Bank of Mexico, Mexico's Central Bank, tried to support the value of its peso by trading dollars for pesos to keep the exchange rate within a predetermined band. A sudden capital flight at the beginning of December 1994 led to a loss of $1.5 billion in foreign reserves in three days, and the Bank of Mexico had to adopt a floating exchange rate by the end of the month. The value of the peso plunged from 3.5 to 6 pesos per US dollar and looked to decrease further unless major stabilization measures were undertaken.

To follow were a series of IMF-supported currency stabilization policies proposed by the Mexican government and supported by the Director of the IMF, Stanley Fischer, who stated that the policies should result in "low inflation, renewed economic growth, and a significant strengthening in the balance of payments" (IMF, 1/95). The plan, which included a decrease in government spending, increase in government revenue, and a decrease in the rate of growth of the money supply, was supported by the largest single IMF credit backing in history, both in amount and overall percentage of member country quota. The plan gave priority to maintaining social programs, including increasing the minimum wage by 10% in April and retaining social security benefits. But the cuts in subsidies, increases in revenues (accomplished through increases in user fees for government-provided utilities) and wage increases which failed to keep pace with inflation may have affected different income groups disproportionately, perhaps worsening income distribution.

Were these measures truly responsible economic policies? It is inevitable that a country undergoing a currency crisis will have to undertake drastic, painful measures to exit the crisis. In the case of Mexico, however, it is unclear that each class of citizen bore the burden to the same extent. Evidence gathered in Monterrey, Mexico during the summer of 1996 will be used to analyze the effects of this stabilization package on different income classes.

THEORY SUPPORTING THE IMF PLAN

The IMF policies may be illustrated by IS-LM analysis to predict the effects of the reduction in the budget deficit, the devaluation, and the reduction in money supply growth that the IMF recommends. In this framework, the goals of the package (namely an improvement in the trade balance and controlling the inflation rate) are achievable. The reduction of the budget deficit, whether accomplished through a reduction in government spending or an increase in government income by increasing taxes or user fees, will shift back the aggregate demand curve and lower output. This decrease in aggregate demand will lower interest rates and improve the trade balance by decreasing demand for imports. The currency

BEST COPY AVAILABLE

devaluation, by making Mexican goods cheaper relative to other nations' and other nations' goods relatively more expensive, would also improve the trade balance by increasing exports and decreasing imports. A reduction in the growth of the money supply would put upward pressure on the domestic interest rate, reducing inflationary pressures.

According to the standard Keynesian IS-LM analysis, therefore, the currency stabilization policy suggested by the IMF will tend to reduce the trade deficit and curb inflation. These results will most likely come at the cost of some output and thus be recessionary, although the IMF loan would tend to lessen the recessionary effects. Most devaluations are also followed by a temporary increase in the inflation rate, despite attempts to curb inflationary effects. An important question, therefore, is how the costs of the policy are distributed throughout the economy. The IS-LM framework fails to take into account the income distribution changes which may result from changes in relative prices of traded and non-traded goods, increases in user fees, changes in government spending, and the increase in the interest rate. Each element of the stabilization policy will affect different income groups in different ways. It is necessary, therefore, to examine income distribution to determine how the costs associated with the stabilization policy are distributed.

REVIEW OF LITERATURE: STABILIZATION AND INCOME DISTRIBUTION

Demery and Addison provide a theoretical examination of the effects of currency stabilization on income inequality, examining separately devaluation and monetary and fiscal restraint. The net effect of devaluation on income distribution is dependent upon the relative importance of traded and non-traded goods in the consumption basket of different income earners, as the prices of non-tradable goods are not directly affected by the devaluation.

Fiscal restraint achieved by reducing subsidies will adversely affect lower income groups which rely heavily on those subsidies. Similarly, increasing government income by increasing user fees for government services will adversely affect those populations for whom government services represent a large portion of their budget. Monetary restraint will also affect different sectors of the economy. Monetary control instruments will directly affect only the formal banking and monetary sector, in which poor sectors do not often take part.

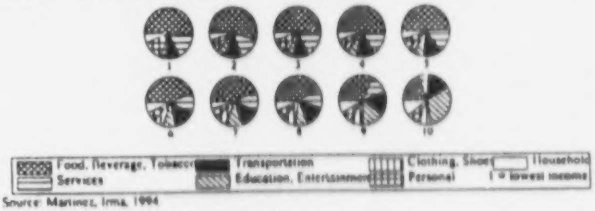
Wage flexibility is an important factor in determining the effects of a decrease in aggregate demand. If the real wage is flexible, firms may be able to maintain employment if workers are willing to take cuts in their real wages. The flexibility of real wages is affected by such factors as unionization and minimum wage legislation. Weaker unions and an unorganized labor force have less ability to bargain and maintain their real wages; this is probably the case in Mexico, where unions are thought to be corrupt and not serve the best interests of workers.

A stabilization policy may initially increase poverty, but in the long run the poor may benefit if the policy leads to sustainable long-term development. The authors call for analysis of empirical evidence to determine whether those who bear the immediate costs of adjustment benefit in the long run.

EMPIRICAL EVIDENCE: PRICES

The data to be analyzed were collected in Monterrey, Mexico during the summer of 1996. Sixty interviews were conducted with workers, plant managers, and economists to determine the effects of the 1994 crisis on small businesses and workers. Monthly price data for 90 products from 1994-1996 and a detailed budget survey of 1000 household heads in Monterrey conducted by the Autonomous University of Nuevo Leon (UANL) were used to calculate price indices for different income groups. Because 1994 was a relatively stable economic year in terms of income and price predictability, the results of the survey will be used to show relatively desirable economic and household budget conditions. It should be noted, however, that income distribution in Monterrey during the time of the survey was not optimal. The poorest quartile of households received 4.73% of total income, while the richest quartile received 55.7%, corresponding to a Gini coefficient of 0.4846. Thus any regressive income or purchasing power effects of the stabilization program will be considered harmful by their worsening of an already undesirable situation.

Figure 1 shows the budget divisions for each decile by household income. The poorest deciles are shown to consume food and services as a large part of their budgets, while transportation and clothing make up a larger part of household budgets as incomes increase.



Source: Martinez, Irma, 1994

Figure 1: Composition of Budget by Income Deciles

Price data were used to price consumer market baskets and create monthly consumer price indices (CPI's) for each decile from 1994 to 1996. Calculated inflation rates are shown in Figure 2 (each two deciles were combined to form 5 quintiles).

Quintile:	1	2	3	4	5
Time Period:					
Jan-May 1994	6.10	6.18	6.10	6.09	6.09
Jan-Aug 1994	8.21	8.34	8.19	8.18	8.17
Jan-Dec 1994	12.53	12.65	12.49	12.46	12.39
Jan-May 1995	6.87	6.89	6.93	6.95	7.05
Jan-Aug 1995	11.04	11.07	11.17	11.22	11.40
Jan-Dec 1995	15.62	15.73	15.89	15.97	16.17

Figure 2: Inflation Rates by Income Quintiles (1 = lowest income)

The differences in CPI's between income groups are negligible. It is also important to note that the CPIs calculated from the Monterrey data are significantly lower than the 35% rates claimed by the government of Mexico. This is most likely from a data inconsistency in certain budget groups, and perhaps from not including debt repayments. The CPI calculations do, however, reflect the impact of price changes on various income groups and are therefore worth analyzing.

Reasons for Differences in Consumer Price Indexes: Food, Beverages, and Tobacco

While the food, beverage, and tobacco division did not experience the highest price increases, the prices of goods in this division continued to increase long after the initial January 1995 shock. Because of the higher proportion of budgets spent on food in the lower income deciles (over 50% of lower income groups' budgets compared with 18-42% in the three highest income deciles), inflation of food prices adversely affected lower-income people. As income increases, a lower proportion of consumers' budgets is spent on milk products, fruits and vegetables, and grains, while consumption of other foods (including imported and domestically produced beverages, processed foods, and tobacco) increases. Middle-income consumers consume the highest proportion of meat products, with consumers on the low and high ends consuming relatively less meat.

Prices of goods in the "other foods" division, which are consumed disproportionately by higher income groups, remained relatively stable throughout the crisis period. Grain prices, although stable during the period immediately following the crisis, experienced high inflation towards the end of 1995 unmatched by a similar increase the preceding year. This also disproportionately affected lower-income groups, who rely more heavily on grain consumption. Food price fluctuations, therefore, adversely affected lower-income consumers through increases in grain and fruit and vegetable prices, and adversely affected middle-income consumers through increases in meat prices. Higher-income people, however, were not disproportionately affected by food price increases because their largest food/beverage/tobacco consumer good, "other goods," did not experience as high an inflation.

Differences in CPI's: Government-Priced Goods and Traded vs. Non-Traded Goods

Figure 3 shows the composition of each decile's budget in terms of government-priced goods (including such services as water and electricity), traded goods, and non-traded goods.

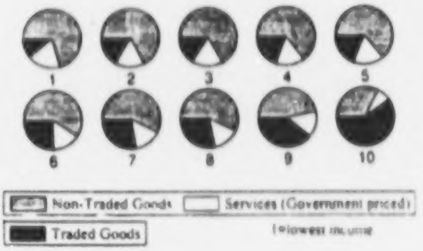


Fig. 3 Composition of Budget, Income Deciles, Monterrey

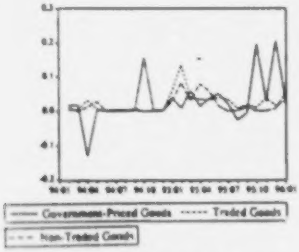

Fig. 4: Rate of Change of Prices Monterrey

(Mexican trade balance data were used to determine whether consumption goods were exported, imported, or not traded.) Although imported-goods prices increased the most immediately following the devaluation, the prices of services and non-traded goods also eventually increased at high rates.

The reliance of lower-income groups on the consumption of services such as telephone, water, electricity, gas, and public transportation makes these groups disproportionately affected by government-induced price increases in user fees for public services. The highest proportion of budget spent on services is represented by the lowest income group, at 16.9%. Proportions decline as income increases, with the 9th decile allotting 12.33% and the highest income only 6.75%. Similarly, lower-income groups are more vulnerable to changes in prices of public transportation (bus or subway). The lowest quintile of income earners in Monterrey spends about 5.5% of its income on public transportation, while the highest spends only 0.68%, concentrating more of its transportation budgets on servicing vehicles they own.

The higher-income groups in Monterrey are shown to be much more dependent on imported goods than lower-income groups. The jump in prices of imports which occurred immediately following the December 1994 devaluation, therefore, adversely affected these import-dependent higher-income groups. Import prices in general increased more than non-traded and government-priced goods during the period immediately following the devaluation, which could be the reason that import-dependent high-income groups experienced the highest increases in their inflation rates during this time.

In the long run, however, import prices began to level out by mid-1995 to match price changes in non-traded goods. Thus the traded vs. non-traded aspect of each consumption good lost importance as prices leveled off. The effects of stabilization on high-income groups, therefore, were concentrated in the short run. As user fees were increased by the government, lower income groups began to see the price of their market baskets increase.

In conclusion, the price and budget data would indicate that high income groups in Monterrey were adversely affected by the devaluation in the short run by their dependence on imports, whose prices increased drastically. In the long run, however, the peso stabilization policy adversely affected low-income groups by increasing the cost of their market basket as the inflation of traded and non-traded goods' prices subsided.

EMPIRICAL EVIDENCE: INTEREST RATES

The effects of interest rates on income distribution during the peso stabilization program are ambiguous. Because the interest rates on credit cards and many bank loans were pegged to the dollar, interest rates increased drastically following the exchange rate devaluation in December 1994, jumping from below 20% to more than 80% in March 1995. Because lower-income groups are not largely directly involved with the formal banking sector in Mexico, the increase in interest rates did not affect them very much. Spending on credit card debt in the lowest quintile is only 0.5% of this quintile's total budget expenditure, and only 1.81% of the second-lowest quintile's budget. The third and fifth quintiles, however, spend 3-4% of their budgets on credit card debt, which increased greatly when interest rates increased drastically in January 1995. Thus middle and high-income consumers were adversely affected by the increase in the interest rate. Inasmuch as the highest income earners are lenders, however, the increase in variable interest rates benefited lenders because debt repayment was not fixed but flexible. The data is insufficient to determine whether high-income groups benefited or lost from the increase in interest rates.

EMPIRICAL EVIDENCE: UNEMPLOYMENT

Data was collected from INEGI (Mexico's national census bureau) and the 60 interviews to determine changes in wages and employment in Monterrey during the economic stabilization program. It should first be noted that unemployment worsened for many months after the initial stabilization program, reaching a peak of 11% in August 1995 from 4% in February. The employment effects of the stabilization program, therefore, lasted at least 8 months. Although employment in all jobs was reduced during the stabilization period, young Monterrey workers, especially men, were disproportionately unemployed. For both men and women, young workers ages 12-25 were more likely to be unemployed than middle-aged workers during the destabilization period. Because young workers are most likely unskilled and poorly paid, these high rates of unemployment were most likely concentrated in the poorer sectors of the population.

Not only was unemployment persisting at a high rate months after the devaluation, but average wages fell until August 1995. Beginning in March 1995, the percentage of Mexican workers employed below the minimum wage or from 1 to 2 times the minimum wage increased, while the percentage of workers employed at more than 2 times the minimum wage decreased. Thus average nominal wages were decreasing and prices were increasing, signifying that the real wage was being eroded.

Interview data with economists and business owners/managers in Monterrey supported the notion that wage increases occur only with minimum wage increases. Most nominal wage increases, which generally occur with minimum wage increases, fall below minimum wage percent increases, regardless of wage level, as is shown in Figure 5.

Figure 5. Percent Change in Nominal wages vs. Inflation for Various Jobs, Monterrey

The vast majority of nominal wage increases lie below minimum wage increases regardless of wage amount. Thus there exists an across-the-board general real wage decrease in Mexico which was amplified during the stabilization period due to the high rates of inflation.

CONCLUSIONS

The IMF has recognized that its programs "have not in general been inimical to the goal of improving distribution of income" (Sisson, 36). Its consideration of the effects of policy on the poor is shown by its attention to the maintenance of social security systems and job creation included in its 1995 Mexico plan. But the theory the IMF uses to support its currency stabilization programs fails to include the effects of its policies on income distribution, which we have shown to be influential. The high inflation, slow wage increases, decreases in subsidies, increases in user fees, and skyrocketing interest rates which accompanied the 1995 peso stabilization program, and which often characterize currency stabilization programs, affected different income groups in different ways. The poorest sectors of the population in Monterrey were adversely affected by inflation in food prices and increases in user fees for services because these elements represented a large part of their budgets. Young and unskilled workers were unemployed at higher rates than older, skilled (and most likely higher-paid) workers. These regressive income distribution effects, however, were countered by effects of the policy which adversely affected the middle-and higher-income groups, i.e. the increase in the interest rate and the increase in the prices of imported goods consumed largely by the upper classes.

It is important, therefore, for the IMF to recognize the impact of its programs on different income groups so as not to worsen already poor income distribution. Alternatives to certain aspects of the program proved regressive could be proposed. In Mexico, this might have included slower increases in user fees, fewer subsidy reductions in food staples, and more minimum wage increases to reduce the drop in real wages. While the IMF/Mexican government program did indeed address its social costs, the measures proposed may actually have hurt the people these authorities claimed to want to protect.

Tests of the Induced Innovation
Hypothesis In Indian Agriculture

Anthony Walsh

Department of Economics
Furman University
3300 Poinsett Highway
Greenville, SC 29613

Faculty Advisor

Dr. Kailash Khandke

Economic theory suggests that technology and innovation are the most important factors explaining productivity and growth. The induced innovation hypothesis suggests that research activity can ensure the efficient allocation of resources towards new technology, thus saving the scarce and relatively more expensive factors of production. The Indian economy presents an extremely good case for tests of induced innovation following the Green Revolution in the early 1970's. This study uses cross-sectional data from 53 districts from the main agricultural areas of the country to test this hypothesis. The results are consistent with the hypothesis, and there is basic support for the contention that relative factor prices influence the direction of technological change in the Indian economy.

INTRODUCTION

Agricultural development which stems from technological change and innovation is one of the most important factors which explain growth and productivity in developing countries. New technology and innovation arise from both public and private research. Research is an activity that is generally expensive. Hence there is an urgent need to allocate research expenditure so as to save the relatively scarce factors of production. The induced innovation hypothesis claims that research activity can ensure the efficient allocation of resources which saves the scarce or more expensive factors of production. For example, an increase in the price of fertilizer will lead to research and innovations that develop new technologies aimed at saving the use of fertilizers. In other words, developing technologies that promote the use of other factors such as land and machinery.

Furthermore, Hayami and Ruttan (1970), who first applied the induced innovation hypothesis, argue that research develops technologies that are consistent with the demand for crops in developing agricultural economies. Since the work of Hayami and Ruttan (1970), various economists have tested the induced innovation hypothesis. These include studies on the United States and Japan by Binswanger (1974) and Binswanger and Ruttan (1978). There are a few studies on developing agricultural economies. These include studies of Egypt by Antle and Crissman (1988) and, Justin Lin's (1991, 1995) papers on China. More recently, Olmstead and Rhode (1993) and Koppel (1995) have questioned whether the induced innovation hypothesis is the right framework for analyzing agricultural development and the diffusion of agricultural technology.

Given these studies, there have been few attempts to look at the link between innovation and agricultural development in the Indian economy. This paper uses the induced innovation hypothesis to examine technological changes in Indian agriculture following the Green Revolution in the early 1970's. The data set is a cross-section of 53 districts in India from the early 1970's for the states of Punjab, Haryana, Tamil Nadu, and Maharashtra.

REVIEW OF INDUCED INNOVATION LITERATURE

Hayami and Ruttan (1970) found that a decrease in the price of land and machinery relative to wages led to the increased substitution of land and power for labor in the United States. Binswanger (1974) found that machinery, labor, and fertilizers were very responsive to changes in factor prices in the United States. Antle and Crissman's (1988) study of Egypt reveals that induced innovation may not be as applicable in the short run as compared to the long run. The reason for this result is that farmers may perceive changes in factor prices to be

BEST COPY AVAILABLE

permanent Thus, they may alter their demand for a particular factor more so than if they viewed the factor price change as temporary Olmstead and Rhode (1993) question the validity of the induced innovation hypothesis in examining agricultural development In particular, they emphasize that it is necessary to look at the role of changing crop patterns in explaining the utilization of factors

DATA AND EQUATIONS

This section focuses on capturing technological change in Indian agriculture The four states of Punjab, Haryana, Tamil Nadu, and Maharashtra were chosen because they were more involved in the Green Revolution than most other states The data consist of 53 districts from these states between 1973 and 1975, a time at which the Green Revolution was applied intensively in the Indian economy The aim is to derive a production relationship which includes land, labor, machinery, and fertilizer Since innovations are expected to take time, the equations below introduce a lag structure These relationships can be explained by the following functional forms

$$F/A = a_0 + a_1(PF/PA)_t + a_2(PF/PA)_{t-1} + a_3(PM/PL)_{t-1} + a_4(PA/PL)_{t-1} \quad (1)$$

$$M/L = b_0 + b_1(PM/PL)_t + b_2(PM/PL)_{t-1} + b_3(PF/PA)_{t-1} + b_4(PA/PL)_{t-1} \quad (2)$$

Equations (1) and (2) are tests of the induced innovation hypothesis in which

F/A = ratio of the quantities of fertilizer (F) to the quantities of land (A)
M/L = ratio of the quantities of machinery (M) to the quantities of labor (L)
PF/PA = ratio of the price of fertilizer (PF) to the price of land (PA)
PM/PL = ratio of the price of machinery (PM) to the price of labor (PL)
PA/PL = ratio of the price of land (PA) to the price of labor (PL)

In equation (1), which captures biological technological change, if the price of fertilizer rises relative to the price of land, farmers will use less fertilizer So, we can expect a negative relationship between (F/A) and (PF/PA) If the price of machinery relative to the price of land rises, we can expect farmers to substitute fertilizers for machines Hence, the expected sign between (F/A) and (PM/PL) is positive Finally, if the price of land relative to the price of labor rises, once again we can expect farmers to substitute fertilizer for land We expect similar relationships for equation (2), which captures mechanical technological change

The parameter estimates in equations (1) and (2) may be viewed as the elasticities of substitution for the given set of factors While these equations are an adequate test of the induced innovation hypothesis, they fail to capture the role of research in developing new technologies in agricultural economies Research institutions, both private and public, may allocate resources towards saving the scarce factors and increasing yields in various crops Since rice is one of the main crops in which the Green Revolution was applied intensively, equation (3) is aimed at capturing the relationship between the quantities of rice, the price of rice, research in biological factors, rainfall, research in rice, area of land devoted to rice, and the percentage area under high yielding varieties of rice used in each of the 53 districts Accordingly, equation (3) may be specified as follows

$$QRICE = c_0 + c_1ARICE_t + c_2PHYVRICE_t + c_3RESCHEM_t + c_4RESRICE_{t-1} + c_5RAIN_t + c_6PRICE_t \quad (3)$$

where
QRICE = the quantity of rice
ARICE = the area of land under rice
PHYVRICE = the percentage area under high-yielding varieties of rice used
RESCHEM = research spending in the fertilizer industry
RESRICE = state specific research in rice
RAIN = rainfall
PRICE = the price of rice

Equations (1), (2), and (3) were estimated using ordinary least squares The parameter estimates and results are shown and discussed in the section below

637 BEST COPY AVAILABLE

RESULTS

The results from the induced innovation models, especially equation (1) and (3), are good Table 1 summarizes the results from the biological technological change model where the ratio of the quantity of fertilizer to land (F/A) in each district (for the year 1974) is the dependent variable Given that this data is a cross-section of 53 districts, the R^2 of 0.4366 is particularly good, i e 43.66% of the variation in the quantity of fertilizers to land ratio is explained by the set of independent variables The ratios of the price of fertilizers to the price of land in both 1974 (PF/PA)$_{74}$ and 1973 (PF/PA)$_{73}$ are significant and the effects are quite strong In particular, a 1% increase in the price of the ratios of the price of fertilizers to the price of land (PF/PA)$_{74}$ led to a 0.63% decrease in fertilizer use However, the positive sign for 1973 is surprising Suppose that the price of fertilizer was high in 1973 and that farmers viewed this change in price as temporary If so, they would postpone their purchases of fertilizer until 1974 Such a scenario could explain the positive relationship between (F/A)$_{74}$ and (PF/PA)$_{73}$ This seems to suggest that there is evidence in India to support Antle and Crissman's (1988) hypothesis that farmers understand the notion of temporary and permanent changes in prices The coefficient of the ratio of the price of machinery relative to the price of labor (PM/PL)$_{73}$ was negative, but insignificant at the 5% level as indicated by the t-statistic of 1.84 Again, this result is contrary to expectation If (PM/PL) in 1973 was high, it is possible that farmers bought fertilizer in the 1973 to substitute for the high-priced machines Therefore, they did not need as much fertilizer in 1974 This could explain the negative relationship found between (F/A)$_{74}$ and (PM/PL)$_{73}$ Finally, the coefficient of the ratio of the price of land relative to the price of labor (PA/PL)$_{73}$ was positive as expected, but insignificant

TABLE 1 LAGGED MODEL FOR BIOLOGICAL TECHNOLOGICAL CHANGE
Dependent variable is F/A (Quantity of Fertilizer/Quantity of Land)

Variable	Coefficient	t-statistic
Constant	21.3804	4.2839*
(PF/PA)$_{74}$	-0.6346	-4.0221*
(PF/PA)$_{73}$	0.7039	2.6853*
(PM/PL)$_{73}$	-0.0042	-1.8436
(PA/PL)$_{73}$	0.1386	0.9191
R^2	0.4366	

* significant at 5% level

Table 2 summarizes the results from the mechanical technological change model of induced innovation While the R^2 of 0.5203 indicates a good fit, none of the independent variables is significant Therefore, the results here seem to corroborate the findings from equation (1) that there is a poor link between mechanical change and fertilizer use between 1973 and 1974 in the Indian economy

TABLE 2 LAGGED MODEL FOR MECHANICAL TECHNOLOGICAL CHANGE
Dependent Variable is M/L (Machines/Labor)

Variable	Coefficient	t-statistic
Constant	647.5960	5.3386*
(PM/PL)$_{74}$	-0.0419	-0.6757
(PM/PL)$_{73}$	-0.1409	-1.8638
(PF/PA)$_{73}$	-4.0799	-0.8469
(PA/PL)$_{73}$	1.3168	0.3448
R^2	0.5203	

* significant at 5% level

Research needs to be explicitly considered to test the induced innovation hypothesis effectively since relative prices as in equations (1) and (2) are not the only factors which influence innovation For example, research on fertilizer or high-yielding varieties (HYV) of seeds has been known to increase greatly the yields of various crops throughout the world

BEST COPY AVAILABLE

Equation (3), which uses data from each of the 53 districts from 1975, focuses on rice since it is a major crop of India. Two kinds of research variables, (RESCHEM) and (RESRICE), are included in equation (3) along with other important control variables such as the price of rice, rainfall, and percentage area under high yielding varieties of rice. (RESCHEM) measures the research spending by private firms in fertilizers and (RESRICE) is an index of the public research in rice in each of the four states in this analysis. This index includes budget data, expenditures, and publications resulting from research in the area of rice. It is assumed that research in rice takes time to have an effect on yields, but research in fertilizer may not take much time to apply. Hence, in equation (3), (RESCHEM) is viewed contemporaneously while (RESRICE) is introduced with a lag.

For this equation, if the area of land used for rice increases, the quantity of rice will obviously increase. So, there is a positive relationship between (ARICE)$_{75}$ and (QRICE). Similarly, if the percentage of high-yielding varieties of rice used increases, the quantity of rice will increase. So, there is a positive relationship between (PHYVRICE)$_{75}$ and (QRICE). If private research betters the manner in which fertilizers are applied in growing rice, the quantity of rice will increase. Table 3 shows that the quantity of rice (QRICE) is significantly related to the area under rice (ARICE)$_{75}$, the percentage of high yielding varieties under rice (PHYVRICE)$_{75}$, and the private research in fertilizers (RESCHEM)$_{75}$. The model is an extremely good fit with an R^2 of 0.9736. The effect of research in fertilizers (RESCHEM)$_{75}$ is strong. A 1 % increase in expenditure on research increases the quantity of rice produced in each state by 3.37%. Finally, the signs on (RESRICE)$_{74}$ and (RAIN) are negative and, therefore, contrary to expectation. However, they are both insignificant at the 5% level.

TABLE 3 MODEL FOR RICE RESEARCH
Dependent variable is QRICE (the quantity of rice)

Variable	Coefficient	t-statistic

RAIN	-0.0113	-1.2519
PRICE	-0.1659	-0.7264
R^2	0.9736	

* significant at 5% level

CONCLUSIONS

Since the induced innovation hypothesis claims that relative prices of factors of production affect quantities of these factors, equation (1) supports the induced innovation hypothesis in the Indian economy. From equation (1), we know that relative changes in the ratio of the price of fertilizer to the price of land do affect the quantity of fertilizer used. It is clear, though, that the Indian farmer understands the difference between temporary and permanent changes in price. Also, from equation (3), there is evidence to support the claim that research influences quantities and yields of crops. In particular for the Indian economy, the quantity of rice is significantly influenced by private research in fertilizer use (RESCHEM). While research on high yielding varieties of rice (RESRICE) should significantly affect rice yields, it is difficult to measure and quantify research output from a particular crop. In any case, we expect research on fertilizer to affect yields of most crops positively. The empirical models show basic support for the induced innovation hypothesis. Thus, we can conclude that the induced innovation hypothesis is the correct framework for analyzing agricultural change and development in the Indian economy.

A Qualitative Study of The 1994 Voter Turnout In Prince George's County Executive Election

Dr. Abdul Karim Bangura

This study examines the 1994 voter turnout in Prince George's County executive election. The data collected for this study covered the phenomenon in which Prince George's County voters turned out in record numbers to elect their first Black County Executive. The substantive findings from this research suggest hat increased voter turnout was attributed to recently enacted term limitation measures and Black majority poised to elect the first Black County Executive.

INTRODUCTION

Unlike previous studies on voting behavior which concentrated on the national level (e.g.) (Teixeira, 1992; Piven and Cloward, 1988), this study examines such behavior at the local level. The 1994 Prince George's County Executive election brought dramatic change in the county, as an almost unprecedented number of new faces brought into the fray by recently enacted term limits nearly overwhelmed the voters with choices. Throughout Prince George's 1994 election, officials said high voter turnout was something uncommon in off-year elections (i.e. non-presidential election year).

Thus, this study seeks to examine the rate of voter turnout in the 1994 Prince George's County Executive election and why the rate of voter turnout was dramatically high in an off-year election. This election was the culmination of a decade-long march to political power by African Americans in the affluent Washington suburb. The election of Wayne Curry represented the coming of age politically of the black community. Unlike a city like Detroit or Washington DC, Prince George's County is a jurisdiction where there has been a steady growth of the middle class. So,,the major question here is this: Why was there such a tremendous voter turnout for this 1994 County Executive election?

Prince George's County saw in 1994 has seen the most competitive Democratic primary ever campaign since the county began electing County Executives in 1971. With three-term incumbent Parris N. Glendening seeking the governorship, the vacancy in the county's top elected post prompted a power struggle featuring an array of colorful personalities and racial undercurrents (MacGlashan 1994).

Dramatic demographic changes have altered Prince George's in the last two decades. Once a more rural, predominately white jurisdiction, Prince George's has seen it's character and composition change with the influx of middle cases Black families moving from the District of Columbia, prompting some Black leaders to say it is time for an African American County Executive. But the dramatic exodus of African American families from the District into

Prince George's transformed the 1994 campaign into a symbol of racial empowerment and catapulted Curry into office (Mercurio 1994a).

THEORETICAL FRAMEWORK

As stated earlier, this study seeks to understand the phenomena in which Prince George's County voters turned out in record numbers to elect their first Black County Executive. "The election of a Black mayor often represented a hollow victory in the sense that blacks were almost winning, when whites were giving up on the city," said University of Maryland College Park professor Bart Landry, who has done extensive research on the black middle class (The Washington Post, Nov. 13, 1994). The Immediate question then is the following: How can this electoral victory be analyzed systematically? A Theoretical Approach that has shown a great deal of promise in this area is Voting Behavior.

Voting Behavior

As Hertbert Winter and Thomas Bellows (1985) show, the significance of voting varies with the importance of elections in determining winning candidates. Many Western countries report turnouts in excess of 80 percent; on the other hand, United States congressional elections in nonpresidential election years draw between 30.1 percent and 46.1 percent during the past six decades. In order to delineate these determinants, one must investigate a major question: Why do some people vote?

Why Some People Vote

Ethnicity. In the United States, for example, not many decades ago there was a marked difference in the voting patterns of African-Americans and European-Americans; African-American voting rates were much lower. A great deal of this has changed as income and education evels of African-Americans have risen. Also, the Voting Rights Act of 1965 helped in lowering the barriers placed in the way of African-American registration, especially in the South. To encourage African-Americans to register and vote in 1984, the Rev. Jesse Jackson campaigned doggedly for the Democratic nomination, even though he knew he had no chance of winning. Now, nationwide African-American turnout is closer to that of European-Americans. Of particular importance is this development is the fact that African-Americans have learned the value of their votes. Many racist European-American politicians got the message and have become respectful toward their African-American constituents. Chicanos have quickly learned to register and vote.

Income Level and Education (or Class). In the United States, citizens with large incomes are more likely to vote than those who are less affluent. Also, citizens who are well educated are more likely to vote than those who dropped out of secondary or high school. Even though certain voters often combine the two characteristics, the two influence voting in different ways. The former has to dowith having a stake in election outcomes; the latter has to do with the broader question of interest and sophistication.

Age. Young people under the age of 25 typically feel less politically involved compared to those who are older. Consequently, young people tend to vote less. By 1985, about half of the American citizen 18 to 25 years of age, for example, had not registered to vote(Cord et al 1985).

In 1971, the Twenty-sixth Amendment to the United States Constitution lowered the American voting age from 21 to 18. At almost the same time, most other democracies did the same. In all these countries, the results were similar to that of the United States: the newly enfranchised young people did not vote as much as thier elders (Cord et al 1985).

Area of Residence. In most democracies, the fact that citizens living in urban areas tend to vote more than those living in rural areas is hardly surprising. This reflects the easier accessibility of voting booths in the urban areas, where a relatively smaller area (as in New York City) can comprise a voting district with the same population as a rural district of several square miles (as in Alaska).

Gender. In the past, males were more likely to vote than females in almost every Western sociecty. This was due, in large part, to the fact that females had only comparatively recently won the right to vote in these socities. In Switzerland, for example, it was not until suffrage was granted in the United States after a great deal of struggle by women, the gap between male and female voter turnouts has been narrowing precipitously (Cord et al 1985).

ANALYSIS

Ethnicity. Once a more rural, predominantly white jurisdiction, Prince George's has seen its character and composition change with the influx of middle class Black families moving from the District of Columbia, prompting some black leaders to say it is time for an African-American County Executive. It has become a jurisdiction with its first African-American majority since 1860, accounting for 51 percent of the population in the last census. A major finding of a Washington Post survey (Sept.18, 1994) is that race continues to be a major factor in voting patterns in Prince George's County. Roughly 25 percent of those interviewed before the election said it was important that the next County Executive be black. Wayne Curry, a lawyer who epitomizes the County's new breed of African American professionals, considered himself ready. In the democratic primary, Wayne Curry won 54 percent of the African American vote. In a Washington Post poll, nine out of ten black voters cast ballots for one of the Black candidates in the race. And blacks were more than twice as likely as white voters to say that the race of the candidates was an important factor in determining their vote (Washington Post, Sept; 18, 1994). "I feel blacks have more opportunities in Prince George's than the whites," said Wittenhauer, a 44 years old white resident whose company sells computers, fax machines and typewriters. She had hoped Curry will scrap the County's preference program, which allows minorities with slightly higher bids to win contracts (Washington Post, Nov. 13,1994).

Income level and Education. The White majority in Prince George's County of the 1970's is long gone; they moved mostly to the County's south and southeast neighbors, Calvert and Charles Counties. Prince George's 730,000 residents are now 52 percent African American and three percent other nonwhites (Washington Post, Sept. 18, 1994). By all accounts, the new Black majority is more sophisticated, more educated, and more affluent on average than the Whites they replaced. And they are not about to march in lockstep with anybody, Black or White. Their worries mirror the concerns of any middle and upper-middle class community: they want better schools, less crime, and lower taxes. Curry did well with affluent Black voters, claiming 54 percent of the vote among Blacks who earned $50,000 or more, while receiving 21 percent of the vote from whites who earned $50,000 or more. Less than half the voters surveyed (by Washington Post) said growth and development were very important in determining their vote, compared with 86 percent who said crime a was very important determinant. Crime was a the issue Curry repeatedly said was the number one problem facing the county (Washington Post, Sept. 18, 1994).

Age. Wayne Curry, the youngest candidate in the race, ran stron among younger voters, claiming half of all votes cast by those 30 or younger. But among voters over age 60, the only age group where white voters remain a clear majority in the county, Curry won just 29 percent of the vote. The major issue for older voters was tax increases. And the major issue for younger voters was opportunities for the county's growth and development (Washington Post, Sept. 18,1994).

Area of Residence. In the white Republican strongholds of Laurel, Lanham Seabrook and Bowie, Wayne Curry received fewer vote. In the Black democratic strongholds of Landover, Capital Heights, Mitchellville, Oxon Hill, Temple Hills and Fort Washington, Curry received the majority of his votes. Curry was interested in tackling broader social and economic goals, particular encouraging the revitalization of communities close to the District of Columbia. He said such economic redevelopment is critical to addressing the rising crime rate in Prince George's. "We've got most of the expanding crime in the inner Beltway," Curry said, "And it just coincidentally is the same area we ignored in terms of economic growth and opportunity"(Washington Post, Nov. 3, 1994).

Gender. Gender was not a significant variable. The 1994 County Executive election, as most of the votes followed racial lines. Most African American men and women voted Democrat, while most white men and women voted Republican.

CONCLUSION

Based on the Preceding Analysis, a number of Conclusions can be drawn. First, race was a major factor in the 1994 Prince George's County Executive Election. Second, the new Black majority saw Wayne Curry as someone with their similar socio-economic status. Third, the young voters were more likely to vote for Curry than voters over 60. Fourth, as expected, Curry, being a Democrat, did better in Democratic strongholds than Republican strongholds. Finally, Gender was not a significant variable in this election.

Clearly then, the election of the first African American County Executive in Prince George's County was a culmination of a decade-long march to political power by Backs in the affluent Washington suburb. "It is the natural evolution of urban politics in the way American has developed," said Alvin Thornton, a political science professor at Howard University. But while many viewed the county elections as part of a historic power shift towards a new generation of African American professionals, most of the contests were dominated by more specific concerns about curbing crime and improving the quality of education. The increase in voter turnout in the 1994 County Executive election can be attributed to two factors: (1) recently enacted term-limitation measures, which guaranteed that Parris N. Glendening could not seek a fourth term; and (2) a preordained political rite of passage, with the county's new Black majority seemingly was poised to elect the first Black County Executive in Prince George's history.

A Test of the Efficacy of the University of Maryland College Park Affirmative Action Program

Shamica Monique Jackson

Department of History and Government
Bowie State University
Bowie, Maryland 20715

Faculty Advisor
Dr. Abdul Karim Bangura

Employing a multiple, time series regression analysis, the study examines the nature of the Benjamin Banneker Affirmative Action Scholarship Program at the University of Maryland College Park and its efficacy. This was necessary because existing works on affirmative action programs are neither guided by sound methodological analysis nor do they offer empirical evidence about the efficacy of such programs. The substantive findings of this study suggest that there is a positive statistical relationship between the Benjamin Banneker program and the retention and graduation rates of African American students enrolled at the University.

INTRODUCTION

The purpose of this essay is to assess the efficacy of the Benjamin Banneker Affirmative Action Scholarship Program at the University of Maryland College Park. This is important because existing works on affirmative action programs are neither guided by any sound theoretical frameworks nor do they provide empirical evidence to demonstrate the efficacy of these programs. Instead, these idiosyncratic studies (Proponents of Affirmative Action--Fisher 1986, Bergmann 1996, Healy 1996, and the U.S. Department of Education 1996, Opponents of Affirmative Action--Gross 1977, Joyner 1977, Coughlin 1995, Jaschik 1995, LaNoue 1995, and Eastland 1996) concentrate on the ideological/political aspects of these programs. Furthermore, as Thurgood Marshall once noted:

> When the Negro child reaches working age, he finds that America offers him significantly less than it offers his white counterpart. For Negro adults, the unemployment rate is twice that of whites, and the unemployment rate of Negro teenagers is nearly three times that of white teenagers. A Negro male who completes four years of college can expect a median annual income of merely $110 more than a white male who has only a high school diploma. Although Negroes represent 11.5% of the population, they are only 1.2% of the lawyers and judges, 2% of the physicians, 2.3% of the dentist, 1.1% of the engineers and 2.6% of the college and university professors (211).

Therefore, the major questions of the research are as follows: (1) What is the nature of the University of Maryland College Park's Affirmative Action Funding Policy? (2) How do African Americans benefit from this policy? These questions are vital because they will help to determine the nature of the program.

RESEARCH METHODOLOGY

The research methodology that guides this study is quantitative. Considering the major questions of this study, the hypotheses of this research are H1: If affirmative action funding increases, then enrollment rates will increase. H2: If affirmative action funding increases, then the number of Banneker scholars will increase. H3: If affirmative action funding increases, then graduation rates will increase. These hypotheses are linear, directional because they indicate that the values of the variables are apt to increase. The affirmative action funding policy is assumed to have an effect on enrollment rates, the number of Banneker scholars, and graduation rates.

The theoretical framework of this research can be diagrammed as follows:

Enrollment Rates
(Dependent Variable)

Affirmative Action
Funding Policy →
(Independent Variable)

Banneker Scholars
(Dependent Variable)

Graduation Rates
(Dependent Variable)

The independent variable in the preceding theoretical framework is the affirmative action funding policy because it is thought to influence, affect, or cause increases in the enrollment rates, the number of Banneker scholars, and graduation rates, the dependent variables. Therefore, there is one basic assumption in this study: a relationship exists between the independent variable and the dependent variables.

The type of research design used for this is a simple time series design. This design is used because it suggests how the affirmative action funding policy could have increased enrollment rates, the number of Banneker scholars, and graduation rates at the University of Maryland College Park from 1980 to 1994. This design can be diagrammatically represented as follows:

$$X\ O_{1980}\ O_{1994} \qquad [1]$$

where O..O represent observations of the outcome of the independent variable, which is the increasing number in enrollment rates, the number of Banneker scholars, and graduation rates (dependent variables) over a given time. The X represents the effect or independent variable, which is the affirmative action funding policy.

The data source for this study comprises the University of Maryland College Park Institutional Studies (1980-1994). Thus, the type of data collection technique used is document analysis.

DATA ANALYSIS

The data for this study were analyzed in two stages: (1) univariate--looking at one variable at a time, and (2) bivariate--examining two variables at a time. The computer package that was used to compute the data is called the GB-STAT. The statistics used at the univariate stage are the mean and standard deviation. The results of the data generated from the computer runs for these statistics are summarized in Table 1.

TABLE 1. MEAN, STANDARD DEVIATION, VARIANCE, AND COEFFICIENT VARIATION OF VARIABLES

Variable Name	Mean	Standard Dev	Variance	Coef. of Var.
AAP	289536.30	331564.80	1.09	1.14
ERT	2184.50	209.10	43723.35	.09
NBS	23.07	6.40	41.14	.27
GRT	352.21	77.77	6049.40	.22

where:
AAP = Affirmative Action Policy Funding
ERT = Enrollment Rates
NBS = Number of Banneker Scholars
GRT = Graduation Rates

BEST COPY AVAILABLE

From the preceding table, the mean for the funding of the affirmative action policy (the Banneker Scholarship) is $289,536 per year (i.e. less then one percent of the total University average yearly budget of 21,460,000--*Chronicle of Higher Education*, Almanac Issue, September 1, 1995: 62) for the years 1979-1980 to 1993-1994; the standard deviation is $331,564. This variation is not statistically significant at the .05 level. The mean for the enrollment rates is 2,184 students for the given years; the standard deviation is 209 students. This variation also is not statistically significant at the .05 level. Next, the mean for the number of Banneker scholars is 23 students and the standard deviation is 6 students for the given years. Finally, the mean for the graduation rates is 352 students and the standard deviation is 77 students for the years examined. The variations for these variables also are not statistically significant at the .05 level.

The statistic employed for the bivariate analysis is the correlation coefficient for both correlation and regression analyses. The results from the computer runs for this stage are presented in Tables 2 and 3.

TABLE 2: CORRELATION MATRIX

	AAP	ERT	NBS	GRT
AAP	-----	.52106	.79197**	.84752**
ERT	-----	-------	.74659**	.80425**
NBS	-----	-------	-------	.83839**
		**P<.01	*P<.05	

From Table 2, it can be seen that AAP has no correlation with ERT; however, NBS and GRT has a correlation at the .05 level; GRT has a correlation with NBS and GRT at the .05 level; and NBS has a correlation with GRT at the .05 level. it can be seen that AAP has no correlation with ERT; however, NBS and GRT has a correlation at the .05 level; GRT has a correlation with NBS and GRT at the .05 level; and NBS has a correlation with GRT at the .05 level. The results from the computer runs for this technique appear in Table 3.

TABLE 3: LINEAR REGRESSION CORRELATION COEFFICIENTY=ERT, NBS, AND GRT X=AAP

	ERT	NBS	GRT
Unadjusted R^2	.2715	.6272	.7183
Correlation Coeff.	.5211	.7920	.8475
Avona for Prediction F	4.4719	20.1900	30.5965
Chance Probability P	.0561	.0007	.0001
STD Error of Est.		185.7585	

As shown in Table 3, there is a positive and statistically significant relationship between ERT and AAP at the .05 level. In addition, there are similar relationships between NBS and GRT and AAP. The explained variances for these relationships are 52%, 79%, and 84%, respectively.

CONCLUSION

Based on the preceding analysis, it can be summarized that there are positive and statistically significant relationships between AAP and ERT, NBS, and GRT at the .05 level. From this analysis, it is clear that the original hypotheses of this essay can be accepted.

H_1: If affirmative action funding increases, then enrollment rates will increase.

H_2: If affirmative action funding increases, then the number of Banneker scholars will increase.

H_3: If affirmative action funding increases, then graduation rates will increase.

In essence, as the Rev. Dr. Martin Luther King, Jr. once stated, "We have developed an underclass in this nation. And unless this underclass is made a working class, we are going to continue to have problems" (Riley 1991: 61). Therefore, affirmative action policies/programs are necessary in this society to move the African American from a "permanent underclass" to a "middle/upper class."

From Critique to Consensus: Stephen White's Pursuit of a Postmodern Politics

Dr. David Gugin

ABSTRACT

Through an examination of Stephen White's text, Political Theory and Postmodernism, I wish to explore a pluralist political theory that is informed by postmodernism's commitment to otherness and critique of metanarrative. I will specifically address the capacity of post-structuralist critique to challenge narrative and White's conception of justice which understands both a responsibility to act and a responsibility to the other.

DISCUSSION

Postmodernism is one of the most widely used and most frequently misunderstood concepts in contemporary political discourse. Much of this confusion is caused by the number of competing interpretations, its internal contradictions, and lack of consensus as to its origins and political relevance. Many have dismissed postmodernism because it seems to lack a theory of agency. However, I believe it is important for contemporary pluralist politics because of its commitment to otherness and its critique of metanarrative.

There are two primary concerns which have caused some to be skeptical of postmodern critique. First, postmodernism has a self-reflexive, paradoxical nature that tends to contradict or undermine its central assertions. While calling into question the legitimacy of narrative, postmodernism cannot escape the fact that it is, itself, a narrative. Some argue that postmodernism reifies rather than deconstructs cultural dominants because the postmodern critique is limited to the very language and conventions that it is critiquing. In The Politics of Postmodernism, Linda Hutcheon uses art as an analogy to examine this contradiction:

> "This is the paradox of art forms that want to (or feel they have to) speak to a culture from inside it, that believe this to be the only way to reach that culture and make it question its values and its self-constructing representations. Postmodernism aims to be accessible through its overt and self-conscious parodic, historical, and reflexive forms and thus to be an effective force in our culture. Its complicitous critique, then, situates the postmodern squarely within both economic capitalism and cultural humanism — two of the major dominants of the western world." (Hutcheon 13)

Secondly, the problematics of a political theory based on a purely deconstructionist, "anything goes" postmodernism are obvious. Since every possible position is considered equally valid, every possible position must be equally privileged; the only way equal treatment can be given to the myriad of competing narratives is to reject them all as flawed. They are rendered equal, but equal in their unsuitability to inform political action. While initially this may privilege alternative narratives by rendering them equal to the dominant, in the end every narrative is left deconstructed, decentered, or devalued. Hutcheon describes this problem when she discusses how postmodernism is counterproductive to the interests of special interest groups. She states, using the feminist movement as an example:

> "The many feminist social agendas demand a theory of agency, but such a theory is visibly lacking in postmodernism, caught as it is in a certain negativity that may be inherent in any critique of cultural dominants. It has no theory of positive action on a social level; all feminist positions do. To 'de-doxify' is not to act, even if it might be a step toward action or even a necessary precondition of it." (Hutcheon 22)

Based on these critiques, many have dismissed postmodernism as inherently negative, ironic, and useless in the political arena. However, I would like to argue that certain aspects of postmodernism are applicable to contemporary pluralist theory. At this point, I believe a close reading of Stephen White may be of use.

White acknowledges at the beginning of Political Theory and Postmodernism that there are various interpretations of postmodernism's relationship to modernism, and he states early on his focus on the more oppositional approaches. In his introduction, he summarizes modernism's emphasis on reason and will, and briefly explains how these precondition the emergence of the dominant political institutions of the nineteenth and twentieth centuries: industrial capitalism, the liberal state, and Marxism. He then begins his discussion of postmodernism and its influences in a manner reminiscent of Mark Edmundson.

In his article, "Prophet of a New Postmodernism," Edmundson considers the postmodern moment:

> "Perhaps we live at a moment when many people--not just our artists--feel confident of their powers to sift critically through the postmodern world of clashing signs. They can't find certainty, but maybe (like [Salman] Rushdie) they aren't looking for that. In fact, it's possible that there are those (again, like Rushdie) who find the prolific variety of contemporary culture exhilarating." (Edmundson 65)

Although White is hesitant to allow that the latter half of the twentieth century has moved completely and radically into a new way of thinking about ethical and political issues, he does believe that we have reached a "postmodern modernity," or a state in which "our modernity is riven by phenomena that are not easily comprehended within familiar cognitive and social structures" (White 3). He refers to these phenomena and their challenges to traditional ways of thinking as the "postmodern problematic," and, to illustrate the emergence of an ethical-political context that underscores the modern-postmodern tension, he discusses four issues inherent to this problematic.

First there is an "increasing incredulity towards metanarrative," in which metanarrative is defined as:

> "those foundational interpretive schemes that have constituted the ultimate and unquestioned sources for the justification of the scientific, technologic and political projects of the modern world. Such narratives, focusing on God, nature, progress, and emancipation are the anchors of modern life."[1] (White 5)

White cites several examples of growing skepticism toward dominant modes of thought, including the deconstructionist impulse of some contemporary philosophy, critiques of liberalism based on a rejection of the assumption that there exists a universal common good, critiques of Marxism that find the conceptual foundations of Marxism comparable to those of Western capitalism, and the questioning of the belief that man is a rational, willful, conscious being (White 5-6).

Second, there has also arisen a new awareness of the costs of societal rationalization and Western modernization. As an example, White cites welfare activities of the modern state:

> "However benevolent these activities may be in intention, the discourses and institutions that emerge with them often promote a deep and progressive disempowerment of their clients. [and] there is [sometimes] little reason to believe that any whole cloth alternatives will not blindly reproduce disempowering modes of rationalization under new guises." (White 8)

Because of this, White argues that more emphasis is being put on continual self-assessment and reassessment in order to avoid continuing or recreating "discourses and institutions" that marginalize.

White's third phenomenon is the rapidly expanding "new informational technology" which encompasses all forms of the media that "vastly enhance the circulation of images and information" with "political ambivalence." This technology has given rise to two interpretations of technology: first as a method of empowering the individual through decentralizing cultural dominants and second as a tool of corporate capitalism that "structures the consciousness and self-identity of individuals and groups" (White 8-9). White elaborates:

> "The crucial questions then become how this proliferation is structured, which cognitive and behavioral scripts are privileged, and which segments of society are systematically advantaged or disadvantaged in the process." (White 10)

White's last element of the postmodern problematic is the emergence of new social movements concerned not with economic distribution, equality, or compensation, but rather with the recognition, protection, or elevation of certain ways of life and sets of values:

> "The women's movement, antinuclear movement, radical ecology, ethnic movements, homosexuals, and countercultural groups in general all share, at least to some degree, this status, even if they differ in many substantive ways. They all have a somewhat defensive character, as well as a focus on struggling to gain the ability to construct socially their own collective identity ..." (White 10)

These groups tend to foster skepticism toward metanarrative as the deconstruction of social dominants allows a "cognitive space" in which their own agendas are subject to less competition.

These ethical-political changes are also described by Anthony Giddens who states, "Postmodernism may or may not exist as a distinguishable phenomenon, no one can doubt, however, that profound changes are occurring in the institutions of the developed societies, regardless of whether or not these are in the end best designated as post-modernity" (Giddens 21-2). Giddens

BEST COPY AVAILABLE

goes on to summarize the distinction between postmodern culture and sociology that Zygmunt Bauman presents in his text, Intimations of Postmodernity:

> "A post-modern sociology, Bauman argues, should not follow too closely the characteristics of post-modern culture -- in this sense, the aesthetics of post-modernism and the demands of social science are distinct. A sociology which simply mimicked the characteristics of post-modernity would be pluralistic and hermeneutic; it would have no place for what, precisely, is required -- an analysis of the nature of post-modernity itself. As Bauman expresses it, a post-modern sociology can not develop a conception of post-modernity. None the less, sociology has to move away from its "modern" emphasis. It has to become "dialogical", rather than "monological", and it has to recognize its own involvement in the endless reflexivity typical of the post-modern condition." (Giddens 21)

Although White does not directly address Bauman in his text, it is precisely this idea of a postmodern sociology he calls for after discussing these four elements of the postmodern problematic.

In order to develop a pluralist theory that addresses these issues, White cites post-structuralism as the "most prevalent strategy for undermining the status of traditional metanarratives," and uses the debate between traditional structuralist and post-structuralist critiques to develop his understanding of the two senses of responsibility relevant to democratic politics (White 13).

Structuralism's sense of responsibility focuses on action. Based on some criteria, one narrative, perspective, or agenda is chosen over others in order that certain goals may be reached. As White summarizes, this phenomenon, familiar "in our modern, everyday life and implicit in the dominant, Western styles of ethical and political thought...might be called a sense of *responsibility to act* in the world in a justifiable way, a moral-prudential obligation to acquire reliable knowledge and act to achieve practical ends in some defensible manner" (White 20).

Post-structuralism's sense of responsibility, on the other hand, focuses on "the other," i.e. the underprivileged or marginalized. Jacques Derrida notes the Western tendency toward "unquestioned binary options" and shows how privileged narratives are not privileged because of any inherent logic or truthfulness, but because they fulfill someone's ethical-political agenda[2] (White 15). Michel Foucault focuses specifically on history and politics "to show how social institutions give practical force to such discursive distinctions and how such distinctions are reconstituted in radically different ways in different historical periods"[3] (White 17).

When discussing post-structuralism, however, we return to the same problem Linda Hutcheon has with postmodernism: once the subordinate narrative takes on a privileged status because of the deconstruction of competing ones, post-structuralism's responsibility to the other requires its deconstruction as well. Hence, all narratives are rendered equal, but equal only in their invalidity. There can be no ethical-political justification for political action.

This critique only applies, however, if postmodernism is interpreted as synonymous with post-structuralism. White attempts to reduce the distinction between modernism and postmodernism by interpreting the latter as beyond post-structuralist critique and by attacking an either/or approach to the senses of responsibility. He argues that "part of the responsibility to act includes the responsibility to take others into account" (White 29). In other words, he understands Tzvetan Todorov's warning that "we should not so blindly conflate rationalism with dogmatism, nor should we forget that unlimited tolerance does not provide a solution to all our problems" (Todorov 32). White develops this argument further in his treatment of justice, illustrating a way to act politically without dismissing this responsibility to the other.

White focuses on justice because it is an arena in which it is easy to understand why the two senses of responsibility must be integrated. If one commits solely to the modern responsibility to act, one would be required to understand justice as reducible to a predetermined set of policies or principles that would be applicable in any given situation regardless of circumstance or context. If, however, one commits solely to the postmodern responsibility to otherness, the only justice served would be abstract and pragmatic; no action could be taken because there is no mechanism for establishing "just" action. Given these arguments, it becomes apparent that neither approach seems to adequately describe justice, a fusing of the two is required. White offers two possibilities: a rethinking of injustice and an alternative approach to otherness.

White first examines injustice not as a phenomenon secondary to justice, but as a "central and ineliminable feature of the world" because, as Judith Shklar states, "we simply cannot know enough about men or events to fulfill the demands of justice"[4] (White 123). The postmodern skepticism toward totalization is acknowledged as emphasis is placed on the examination of the "power processes" in society that lead to "domination and injustice" and directed away from attempts to find definitive terms for describing justice. However, the modern call to action is not

BEST COPY AVAILABLE

forgotten. White relies on Cicero's conception of injustice that condemns remaining passive when another is acting unjustly; the just individual must act in a way that reduces injustice. White calls this "care" and describes it as "adequately expressed by the sensitivity with which one initially comprehends the specific situation of injustice or suffering; and, second, by the alleviation of the particular burdens" (White 125).

In his second and more developed approach to justice, White emphasizes the importance of a discriminate fostering rather than a mere toleration of otherness. He first argues that we must move beyond John Stuart Mill's understanding of diversity as merely a means to some sort of moral or intellectual progress. Mill's diversity, argues White, is too solidly grounded in the responsibility to act; he tolerates otherness only insofar as it leads to the ends he desires:

> "When tolerance is seen in the purely utilitarian way, Mill does not really disturb (although he does not actually endorse) the traditional attitude of considering tolerance as something we *must bear grudgingly* for the sake of something else; but when tolerance begins to have value in itself, then we should in some sense *celebrate or delight in it.*"[5] (White 128-9)

White therefore argues that we must rethink the other, appreciating diversity in and of itself.

Mark Edmundson also develops an understanding of a politics informed by postmodernism which, like White, emphasizes a sensitivity to and a fostering of otherness, the self-aware rethinking which informs social change, and the emergence of a "creative space" in which discourse may flourish. Using Salman Rushdie's Satanic Verses as an example, Edmundson explains:

> "Rushdie's objective is to stand between these two worlds [England and India] and encourage their fusion; he wants to persuade people on both sides to open themselves to each other, though he's not unsophisticated about the risks involved in such an opening." (Edmundson 66)

Similarly, Edmundson's postmodern impulse is one "in which a critique of old stabilities is combined with a drive toward renewal," one in which "homelessness...is understood as humanity's condition--and one, finally, to be affirmed, because it allows for more metamorphosis, change, and the ability (and the need) to be other than one was" (Edmundson 70).

Edmundson cites Richard Rorty as an example of a pragmatic philosopher who successfully treats this positive postmodernism. He sees much value in Rorty's argument that literature "can give us cues for action, fresh ways to orient our lives, and not only our private lives but our public and political lives as well" (Edmundson 66).

Initially, White's "care" seems to echo Richard Rorty's estimation of moral responsibility. White's approach to justice and Rorty's understanding of morality both value the sort of curiosity Foucault describes in "The Masked Philosopher":

> "Curiosity...evokes 'care'; it evokes the care one takes of what exists and what might exist; a sharpened sense of reality, but one that is never immobilized before it; a readiness to find what surrounds us strange and odd; a certain determination to throw off familiar ways of thought and to look at the same things in a different way."[6] (White 91)

Where White calls for a care that requires that "one draw the other into one's own interpretive frame," a "willingness to hold open an intersubjective space in which difference can unfold in its particularity," and "a hesitancy to 'place' the other quickly and firmly within habitual interpretive molds" (White 99-100), Rorty argues in his text, Contingency, Irony, and Solidarity that "curiosity" is the primary virtue:

> "All that is required to act well is to do what artists are good at -- noticing things that most other people take for granted, seeing the momentary iridescence and not just the underlying formal structure....Knowing the good is just sensing what matters to other people, what their image of good is." (Rorty 159)

The parallel breaks down, however, when each attempt to explain how this curiosity or care comes into play in society. Although White may agree with Edmundson's call for positive postmodernism and Rorty's understanding of the importance of curiosity and critique in the political and aesthetic arenas, White believes that Rorty is, in some ways, unrealistic. White develops a politics that subsumes a theory of agency while Rorty believes that "suffering or injustice 'has merely to be noticed to be remedied'" (White 93). Both understand the responsibility to otherness, but only White understands the importance of the responsibility to act.

White is able to appropriate action into his pluralist theory as he does not commit to an "anything goes" acceptance of all forms of otherness; instead he calls for an approach that is both careful and conscientious. Rather than resort to an idealistic aesthetic approach to politics like Rorty, White attempts to work within a realistic social context:

> "Large complex societies will always be heavily constructed around organizational routines and institutional projects, from the perspective of which the appearance of difference will often elicit more irritation than delight. The more the sway of the responsibility to act dominates a situation, the more this will be the case. The real issue is how to relax the pull of this responsibility before,

BEST COPY AVAILABLE

> within, and after such routines and projects; how to create slack and space within which the mood of delight can flourish. Part of this task will be to think creatively about when, where and how intersubjective difference can be actively fostered." (White 129)

White addresses this challenge by asserting that "at some point, one must have a way of arguing that not all manifestations of otherness should be fostered; some ought to be constrained." He then asserts that both a "global principle of pluralism" and "more specific procedural principles providing further normative guidelines for situations where plural forms of life come into conflict" are crucial to political discourse (White 133).

He recognizes the skepticism postmodernists have toward globalization and again uses his two senses of responsibility to offer a compromise between traditional narrative and post-structuralist critique. White's universal is the responsibility to otherness. When conflict occurs, White calls for action informed by a commitment to care:

> "The mood and measure of such a lightness of care would, first, sustain a commitment toward fostering otherness, born of a deeper understanding of finitude and the delight in difference emerging therefrom. Correspondingly, it would also sustain a commitment to constraint, since the urge to dominate constitutes a refusal to bear witness to one's limits, a refusal to recognize finitude. Actions that dominate or systematically manifest a failure to respect others are a willful forgetting of an inescapable dimension of human being." (White 139)

White then applies these principles to the liberal state by offering an initial sketch of how such a rethinking can aid the process of "reorienting ourselves to our own finitude and the meaning of otherness" (White 147). White calls for a "'deliberately nonneutral' liberal state" that is committed to

> "maintaining a balance of values within its own tradition: a state that 'fosters associative activities.' Such a state has an obligation to 'endorse and sponsor' groups which are likely 'to provide shapes and purposes congenial to shared values' of the liberal tradition: 'voluntary association, pluralism, toleration, separation, privacy, free speech, career open to talents and so on.'" (White 144)

Although there is much still to be developed regarding how this "postmodern modernity" will manifest specifically in government, politics, and economics, I believe White's argument is of great value for several reasons. He recognizes that there have been important economic and socio-political changes which cannot be ignored or attributed to the modern impulse of fifty years ago. He goes beyond considering whether postmodernism is valid or applicable to politics; rather, he examines its useful elements without resorting to a reactionary condemnation of the modern narrative. He understands both the equalizing potential of the poststructuralist critique and the cultural need for some sort of narrative structure. Furthermore, he is not intimidated by their seeming incongruity. The narrative to which he eventually commits combines both a sensitivity to the other and a theory of agency in a way that I believe invokes the curiosity and care essential to contemporary pluralist politics.

ENDNOTES

A Quantitative Study of the High School Attrition in Prince George's County, Maryland

Dorothy Lyons-Wilson

Department of History and Government
Bowie State University
Bowie, Maryland 20715

Faculty Advisor:
Dr. Abdul Karim Bangura

The original intent of this study was to examine high school attrition in Prince George's County, Maryland. The independent variables are average income of parents, parents' educational levels, ethnicity, and gender, and the dependent variable is high school dropout rate. However, due to data paucity, the study was limited to testing for a possible relationship between the median income of parents and the high school dropout rate. The data collected and analyzed after the computer runs determined that the hypothesis that the greater the parents' median income in Prince George's County, the lesser the high school dropout rate, is to be rejected.

INTRODUCTION

Following the tradition of earlier studies on attrition and retention (e.g., Bean 1980, Braxton and Hossler 1988, Naylor and Sanford 1982, Pascarella 1980, Terenzini 1987, and Tinto 1975), the original intent of this study was to examine High School Attrition in Prince George's County, Maryland, using the independent variables, average income of parents, parents' educational levels, ethnicity, and gender, and the dependent variable, high school dropout rate. However, due to data paucity, the study was limited to testing for a possible relationship between the median income of parents and the high school dropout rate.

This essay continues with a review of the nature of the problem and identifies specific variables involved, and develops questions which frame the direction, approach, and scope of the study. In the research methodology section, one hypothesis, a design approach are presented to study the relationship held by these variables. Finally, the actual data collected are analyzed at the univariate and bivariate levels.

NATURE OF THE PROBLEM

Every American must energize to transform this country's priorities. The first priority must be children. According to the Children's Defense Fund, each school day 2,255 American teenagers drop out of school. This is an alarming rate. Prince George's County, is included in this tally. Prince George's County youths drop out of school and join together to take part in criminal activities, such as damaging property, destroying community resources, causing fear in people who live in their neighborhoods, drawing graffiti, dealing in drugs, vandalizing, threatening and assaulting individuals with bodily harm, and driving by and shooting innocent citizens. Youth violence grows from common bonds, such as neighborhood and ethnic backgrounds. Youth gangs are formed when people from neighborhoods and communities hang-out together with idle time on their hands. Most of the violence caused by youths is done by males as opposed to females. This is not to say there are not females involved in youth violence, because they are.

There are programs in Prince George's County that are designed to work with youths involved in violence. The Gang Resistance Education and Training program provides a tool through which youths can grow up to be productive citizens. It is a proactive prevention program aimed directly at youths in the County. It provides them with education and equips them to make positive decisions in life.

RESEARCH METHODOLOGY

Employing a quantitative approach, the theoretical framework tested in this study can be diagrammatically represented as follows:

Median Income of Parents	→	High School Dropout Rate
(Independent Var.)		(Dependent Var.)

There is one independent variable in the preceding theoretical framework: median income of parents. This is the independent variable because it is the measure of the phenomenon that is thought to influence, affect, or cause the dropout rate, the dependent variable. Therefore, the basic assumption in this study is that there is a relationship between the median income of parents and the dropout rate of Prince George's County high school students.

There is one hypothesis being examined in this study based on the preceding problem definition and theoretical framework. This hypothesis is as follows: H1: The greater the median income of parents in Prince George's County, the lesser the high school dropout rate. This hypothesis is one-way directional because it suggests that the average income of parents will affect the high school dropout rate in Prince George's County. The level of analysis is micro because parents' median income and the high school dropout rate are being examined for only one county in the United States.

The research design used in this study is a simple time series design because it suggests how average income of parents could have decreased the dropout rate in Prince George's County, Maryland, from 1991 to 1995. This design can be diagrammatically represented
as follows:

$$X\ O\,1989 \ldots O1995 \qquad [1]$$

where O represents the observation of the outcome of the dependent variable, which is the increasing high school dropout rate over time, and the X represents the effect or independent variable, which is the median income of parents.

The data for the high school dropout rate in Prince George's County School System were obtained from the Prince George's County Public Schools Pupil Accounting & School Boundaries Department. The data for the median income of parents were retrieved from the 1995 Maryland School Performance Program Report.

DATA ANALYSIS

In this examination of the high school dropout rate in Prince George's County as it relates to median income, two stages of data analysis are employed in order to process the data completely. In the univariate analysis, each variable is examined independently of each other and specific values are assigned to it. The bivariate analysis assesses the values given to the two variables and makes a determination whether the two correlate or are related with each other. If a correlation is discovered, the nature of the pattern will tell how the variables are related. The statistical package used to accomplish this analysis is GB-STAT.

The statistics used in the univariate analysis are the mean, or average, and the standard deviation. The results generated from the computer runs for these statistics are summarized in Table 1.

TABLE 1: Mean and Standard Deviation

Variable	Mean	Sample Std. Dev.	Sample Variance	Coef. Of Variation
DROPOU	4.20	.32	.10	.07
MEDINC	48,388	3787.61	1.43	.07

DROPOU = High School Dropout Rate
MEDINC = Median Household Income

Table 1 does not show a consistent pattern for the high school dropout rate, the dependent variable, and the independent variable, median income. Also, the mean dropout rate is 4.2 percent and the mean income is $48,388 from 1990 to 1994.

The coefficient of variation for each variable tells us whether or not the variations within them are statistically significant at the .05. It is interesting to note that when examining DROPOU and MEDINC, the coefficients of variation for both is .07, which is not statistically significant at the .05 level.

Table 2 presents the correlation coefficients for the first part of the bivariate analysis. The idea was to test for the strength of the relationship between the two variables.

TABLE 2: Correlation Matrix

	MEDINC
DROPOU	.64186

**p<.01 *p<.05

An analysis of Table 2 demonstrates the type of correlation between the variables. This is correlation is explained as follows with a correlation coefficient of .64, DROPOU is not statistically correlated with MEDINC at the .05 level.

Table 2 sought only to explain the correlation and the strength of that correlation between the two variables. The direction and significance of the relationship is shown by regression analysis. The following table (3) shows the results derived from the computer run for this procedure.

TABLE 3: Explanation for the Variation in DROPOU

Table 3

DEGREES OF FREEDOM =1 AND 3

WITH X = MEDINC AND Y = DROPOU

From Table 3, it can be seen that in regards to DROPOU as it relates to MEDINC, there is no relationship which is statistically significant at the .05 level. Also, about 41% of the relationship is explained. Thus, the hypothesis tested in this study, H1: The greater the median income of parents in Prince George's County, the lesser the high school dropout rate, is rejected.

CONCLUSION

This study began by defining the attrition problem of high school students in Prince George's County. Second, the research methodology section entails the theoretical framework which helped to narrow the focus and provided the specificity needed to identify a factor which may define the broad problem of high school attrition in Prince George's County. Then, the hypothesis was suggested that there is a relationship between the independent and the dependent variables. At this point, the research design was drawn to show the time frame that each variable was studied. The data collection section explained from which sources the data used were derived. Finally, the last step analyzed the data collected which determined the hypothesis that the greater the parents' median income in Prince George's County, the lesser the high school dropout rate, is to be rejected.

Race in the Balance:
Case Study of Escambia Treating Company

Environmental racism has plagued the communities of African Americans, Native Americans, Mexican Americans, and other ethnic communities in the modern era. The historic lack of political power of people of color has left many communities trapped in environments polluted with toxic waste. Race and ethnic discrimination have greatly influenced the location of toxic waste sites. I examined a chemical waste company in Pensacola Florida as a case study. This paper correlates the racial composition of communities and location of toxic sites. In our quest to achieve environmental justice, we must realize the social importance of the race issue.

> More than 15 million African Americans live in communities with one or more toxic waste site; in fact three out of every five African Americans and Hispanic Americans live in communities with uncontrolled toxic waste sites (According to a study of 41 U.S. communities where the highest level of commercial hazardous waste activity is taking place) (Bullard, 1993).
>
> Race proved to be the most significant factor among variables tested in association with the location of commercial hazardous waste facilities. This represents a consistent national pattern (Gerrard, 1994 p.86). Three out of the five largest commercial hazardous waste landfills in the United States are located in predominantly Black or Hispanic communities. These three landfills account for 40 percent of the total estimated commercial landfill capacity in the nation (Bullard 1993).

Racism is a holistic entity affecting people's lives in almost every aspect. Environmental racism as defined by Benjamin Chavis Jr. is

> racial discrimination in environmental policymaking. It is racial discrimination in the deliberate targeting of communities of color for toxic waste disposal and the siting of polluting industries. It is racial discrimination in the history of excluding people of color from mainstream environmental groups, decision making boards, commissions, and regulatory bodies (Bullard, 1993).

Environmental racism not only affect the living environment of people, but it also affects their health and their overall wellbeing. In order to understand the correlation between toxic waste sites and environmental racism, I have focused on the Escambia Treating Company in Pensacola, Florida. In this paper I will demonstrate the devastating consequences that African Americans face from living in a polluted environment. Through this case study I will also analyze one way in which the community has been empowered to fight back.

Located in a poor African American community, the Escambia Treating Company (ETC) manufactures treated poles for sale to telephone and electric utilities. Founded in 1924, the company specializes in

BEST COPY AVAILABLE

pentachlorophenol and CCA - treated wood poles and piling. Although the company shut down on October 1, 1982, the people of that community are still feeling the effects of the company. The company shut down because the owners felt it was no longer economically profitable. However, many issues in concerning the company have risen (Wittwer, 1982).

The U.S. Environmental Protection Agency (EPA) is still pursuing a 1988 suit against the owner, Charles A. Soule Jr., alleging that he is responsible for hazardous waste violations. The EPA says Soule should determine the extent of damage, pay for the cleanup, and substantial fines. The most serious alleged environmental violation is the release of hazardous compounds into the soil and groundwater at all locations of the plant. In addition, he is accused of operating hazardous-waste facilities without permits, failing to provide liability insurance, and failing to monitor groundwater (Graybiel, 1990). How a company can exist for over 58 years with such drastic and extreme violations and not have been stopped raises questions about how much this company, and the EPA care for the people in that community.

The existence of this company has presented health problems from the day it opened, threatening the lives of children of the past, and children of the future. In an attempt to find exactly what toxins and how much of those toxins are located in the soil, the EPA has tested the soil where the company once stood. Test results showed that the level of toxins in the soil were beyond safe living conditions for the people in that environment, and for people who use the groundwater. The EPA says it needs more testing for dioxin, but a few analyzed samples showed levels way above the residential standard for dioxin cancer risk. With dioxin, counting only the cancer risk is very misleading because research shows that dioxin is a powerful artificial hormone capable of playing havoc with the endocrine system. Small amounts of dioxin might not cause cancer but still result in birth defects, neurological disorders, and immune system damage. Tests also showed the soil and ground water were contaminated with creosote, pentachlorophenol and other chemicals. Creosote, a wood preservative, is toxic and suspected of causing cancer. By considering contaminants separately ignores the synergistic interactions, often the most damaging health effects of all.

"Nobody can tell me that this place is not killing me," is the response of Alberta Snipes (Myers, 1992). The health hazards for the people of this community are atrocious. After suffering this mistreatment for many years, the people of the community decided to fight back. Led by Margaret Williams the people of this community organized CATE, Citizens Against Toxic Exposure. The people of the community do not want special treatment, only equal treatment. The initial problems that this community faced were about skin color and economics, but ultimately the issue is survival itself. The problems are about innocent adult and children victims. In the words of Sammie Jones, who lives a stone's throw from ETC and suffers from breathing problems, "we're talking about human lives, and you don't get but one chance" (Graybiel, 1995).

There is nothing that can be done to vaccinate these residents against living next to a waste dump and/or living next to the essences of a waste dump. "All around the neighbourhood, people are dying of cancer. It is at epidemic proportions. Someone must be held accountable. These are human beings, not guinea pigs," says John Beck, a frustrated resident of the community

BEST COPY AVAILABLE

(Myers, 1992). Residents of these neighbourhoods claim that sixty-four people have died of cancer in the past 10 years. Only nine people in the area died of other causes during that time. Frank Pricket, 55 years old, said 15 to 20 of his neighbours have died of cancer in the past 10 years. The health problems of these residents are so extensive that they indicate a common casual factor.

Initially the EPA failed to acknowledge that their complaints were real. Did the problem stem from people's presenting unreliable information, or was it the result of the EPA not carefully listening. After many meetings and much time, the residents of this community convinced the EPA to begin cleaning up the problems created by ETC. The health complaints of residents have been consistent over many years; however, they soared in October 1991 when EPA officials began excavating the soil to stop groundwater contamination. The EPA proposed that this toxic cleanup site be added to a priority list to receive Superfund status. Superfund sites are hazardous waste areas the EPA has declared priority sites for cleanup. Because of the high levels of toxins, the site has been proposed to be a part of the National Priority List (Basiouny, 1994).

Now that the residents have gotten someone to listen to what they are saying, what is the best solution to the problem? The proposal that CATE suggested was cleaning up the contaminated environment. Well how do you clean such heavily contaminated soil? The approaches that the EPA sought originally were by cleaning or heating the soil. Soil washing treatment is not designed to eliminate contamination, yet it is used to reduce the volume of contaminants in the soil. However, preliminary tests show that cleaning the soil would only eliminate 97 to 98 percent of the pentachlorophenol and 85 to 96 percent of the creosote: enough to past minimal standards, for those toxins. The other method, boiling the soil, would require the soil to be heated at temperatures above 1,800 degrees Fahrenheit. Finally, with the help and agreement of CATE, the EPA decided that the best decision would be to excavate the soil (Lamb, 1992).

Cleanup of the ETC site, began in October 1990. The EPA will spend an estimated $100 million to clean this site. But area residents were concerned that the cleanup would create a greater health problem than leaving it alone (Ashby, 1995). The EPA had to remove over 220,000 cubic yards of contaminated soil. The excavated soil has been put into 20 - to 25-foot mounds that are to be capped. The residents were seemingly not considered in this decision. The only safeguards that were given for the mounds were a 12-foot fence that bears no signs that warn of hazardous waste. The contaminated soil was merely covered by heavy tarps. Accessibility to this soil is unsafe, in fact children have been spotted sliding down the tarp covered pile of toxic waste. Moreover, during the excavation of the soil two residents were relocated because of severe problems with breathing.

As a result of more than four years of dogged persistence and unwavering unity by of the members CATE, the EPA has extended an offer to relocate all families in the area. Although the site has become a part of the Superfund, it could take 2 1/2 to 3 years before the clean will be completed (Bisouny, 1994). In 1996, the EPA announced that in the next year it would move 358 households surrounding the sites for approximately $18 million - one of the largest relocations in Superfund history. The residents of this community will be the first African-American community to be relocated through the U.S. government's Superfund policy, and the site has been selected to serve as a relocation pilot program (Sherrell, 1996).

There are many lasting consequences that ETC has left the city of Pensacola, but the price that the residents of this environment has paid, and will pay is heartbreaking. Money can always be replaced, but health and peace of mind can not be bought. The relocation of these residents also came with many problems. The concerns that are presented by CATE are as follows: 1) One is a proposal to begin demolishing each home as soon as its residents are relocated. The activity could force more contaminants into the air if the soil is disturbed. The residents would prefer that everyone is relocated before buildings and houses are torn down; 2) That officials may simply try and put residents in another low-income, minority areas. How long will it take for the government to realize the severity of every aspect of this situation? Despite the EPA's assurance that things are moving forward, some residents feel they are being stalled because of their color. Myrtle Crowe says, "we got a black face . . if it had been you or your race, you'd been out of here. It's not fair . . . if I'm wrong, I hope God forgives me" (Allman 1997).

Alberta Snipes feels that the proof of a health threat is the white safety suits which cleanup crews wear when working at the site. The proof is in the fact that her skin burned before she was relocated. The cleanup crew has suits, but who or what will protect the residents? How do you repay Shirley Jones' three children who are not allowed to go outside and play? What is to happen to her two-month-old son, whose prenatal exposure forced him to spend 10 days in the hospital after his birth because he could not breathe (Allman, 1997)? What happens to 17-year-old Randy Roberts who has quit the Woodham High School track team because he can't keep up. He doesn't know if it has anything to do with the hazardous cleanup site near his back yard. He just wishes he could run as fast as he used to (Lamb, 1994). Willie Julius Jr. must use his portable oxygen machine and take a wide variety of medications for problems he says can be traced to his exposure to the site (Escobedo, 1996). 75-year-old Robert Lee who has lived in this neighbourhood for 71 years has watched cancer claim his mother, father, stepfather, and uncle (Escobedo, 1996).

Not only have the residents of this community suffered from health problems and must leave their homes, there are also unresolved financial issues. Great amounts of money have been spent on this project: millions of dollars. Unfortunately this project will require many more millions to be successful. The majority of the monies spent have gone toward cleaning the site and not towards the other needs of the residents. For example, Alberta Snipes will receive an estimated $16,000 for her house that was once estimated at a value of $45,000. Are these proper compensations? The residents do not feel that they are. No amount of money can fully compensate the residents for their losses. The community has been fragmented. Many residents run a high risk of no longer being a part of the same community, and children may have to change schools. Fair compensation does not alleviate the loss, but at least it gives the residents a fair starting chance.

In conclusion, we have seen the personal and economic consequences of environmental racism in the case of the Escambia Treating Company's degradation of an African American community in Pensacola. We have also seen how an African American community organized and fought back to repair their health and dignity. I want to close with the challenge which Cornell West offers in his book Race Matters:

In these downbeat times, we need as much hope and

BEST COPY AVAILABLE

> courage as we do vision and analysis; we must accent the best of each other even as we point out the vicious effects of our racial divide and the pernicious consequences of our maldistribution of wealth and power. We simply cannot enter the twenty-first century at each other's throats, even as we acknowledge the weighty forces of racism, patriarchy, economic inequality, homophobia, and ecological abuse on our necks. We are at a crucial crossroad in the history of this nation-and we either hang together by combating these forces that divide and degrade us or we hang separately. Do we have the intelligence, humor, imagination, courage, tolerance, love, respect, and will to meet the challenge? Time will tell None of us alone can save the nation or world. But each of us can make a positive difference if we commit ourselves to do so (Cornell West, 1993).

In Pensacola, Margaret Williams and the Citizens Against Toxic Exposure offer you and me such a vision of hope and courage.

ACKNOWLEDGEMENTS
I would like to thank Mr. Dingo for all his help, Mr. Lumon May for his support and Dr. Carolyn Johnston for her guidance.

Aid in Transition
Explaining Post Cold-War Trends in House Foreign Aid Voting

John R. Baker

The end of the Cold War has brought about a fierce debate within the House of Representatives over the role that foreign assistance should play in American foreign policy. The demise of Cold War bipartisanship has resulted in an intensified battle that seems to be focused more sharply than ever along ideological and party lines. To explore the trends in aid voting, the hypothesis that ideology and party are the strongest factors in members' voting decisions on foreign aid legislation is tested; the assumption that those two factors have increased in importance since 1989 is also examined. Bivariate analysis and logit regression suggest the conclusion that ideology and party are very important factors, but the analysis reveals a number of other important influences on voting, and it fails to support the notion that ideology and party are increasingly important over time.

INTRODUCTION

From the early years of the Cold War, foreign economic assistance was a vital part of American foreign policy. But, in the late 1980s as the Cold War waned and domestic budget deficits mounted, Congress began to reconsider U.S. foreign aid allocations. By the early 1990s, liberal members seemed to be supporting foreign aid much more fervently than those with conservative views. The politics of foreign assistance seemed to be moving in a more partisan and ideological direction. Since 1994, the Republican-dominated House and Senate have quickly adjusted foreign aid priorities; multilateral aid appropriations for FY1996 were 33.6% lower than those for FY1995, and bilateral development aid funding was cut by 17.0% (Nowels, 1996, p. 7). Total foreign aid budgeting for FY1996 was set at $12.8 billion--$5.2 billion less than the FY1986 budget (Nowels, 1996, p. 1). This paper examines empirically the apparent increase in ideological and partisan voting on foreign aid during the past decade. The central hypothesis of this study is that party and ideology have been the most important factors in explaining House foreign aid voting decisions since the end of the Cold War. A secondary hypothesis posits that these two factors have increased in importance after 1989 (for practical purposes, the end of the Cold War), and especially after the Republican "revolution" in 1994.

LITERATURE REVIEW

Previous researchers have differed largely over whether a single dimension of influences adequately explains voting, or whether decision-making is a more complex process that can only be explained by examining a variety of dimensions. Unidimensionalist studies generally explain congressional voting by ideology, as measured by a simple left-right dimension (Schneider, 1979). By contrast, the much larger body of multidimensional research asserts that voting behavior results from the interaction of more than one factor or influence. Although this two-category model for classifying the existing literature is admittedly an oversimplification, it seems to provide the most interesting and complete context for this research.

A number of political scientists have explored congressional voting from the unidimensional perspective. William Shaffer (1980), examining the hypothesis that Democratic members of Congress are "far more liberal" than Republican members, finds that the House demonstrates "substantial partisan ideological cleavages." He finds strong evidence that the House is divided along ideological lines and that those divisions correspond with the divide between the two major parties (1980, p. 55). Herbert Kritzer (1978), in his study of elite actions, concludes that elites demonstrate ideological motivation in their action, especially in voting behavior. Jerrold

Schneider (1979) provides the classic unidimensional model, finding that a left-right ideological model explains voting across all major policy areas.

The multidimensional category includes a much broader array of studies that share the common finding that more than one factor influences congressional voting. Influences examined in multidimensional studies include constituency interests, executive branch pressures (Kingdon, 1989), other members (Kau and Rubin, 1979), reelection concerns (Arnold, 1990), lobbyists' campaign contributions (Schroedel, 1986) and party affiliation (Cox and McCubbins, 1991), in addition to ideology and party affiliation. Several of the multidimensional researchers have focused on the varying importance of factors by policy area (e.g., Kozak, 1984).

Finally, political scientists have examined congressional voting on foreign affairs issues in particular from both the unidimensionalist and the multidimensionalist perspectives. Schneider finds that voting on foreign affairs issues follows his overall ideological model. Clausen (1973), by contrast, finds that presidential position and constituency interest are stronger influences than ideology. McCormick and Wittkopf provide an analysis that is especially relevant to this study. They examine the change in partisan and ideological foreign affairs voting before and after the Vietnam war; they find support for the expected increase in partisan aid voting, and they also find that "ideology is an especially strong predictor of foreign aid voting in both chambers" of Congress across the time period (1992, p. 46).

This study proceeds from the assumption that the multidimensional view has received more empirical support, and therefore accounts for a variety of possible influences on foreign aid voting in the logit regression analysis. The importance of the contextual, policy-specific analyses is also acknowledged, and that body of research corresponds with an obvious underlying assumption of this study that members behave in specific, unique ways when they vote on foreign aid legislation, thus obligating a policy-specific inquiry.

RESEARCH METHODS

A series of House votes on the Foreign Operations Appropriations Act serves as the dependent variable for this study. The votes span a period of 9 years and were taken in the 100th through the 104th Congresses. The nine roll-calls funded United States foreign assistance for fiscal years 1989-1997. The independent variable of party was also coded as a simple dichotomous variable, Democrat or Republican (0=Republican, 1=Democrat). Independents and vacant seats were entered as missing data. To measure the ideology independent variable, Americans for Democratic Action (ADA) scores for individual members were employed (ADA scores provide an ideological measure of each member based on prior voting). In order to examine the relative influence of party and ideology on voting, an array of other important factors have been included in this study. One of the most important such factors, geographical region (represented in this study by four categories--northeast, south, midwest, and west), seems to be suggested by the overall dispersion of the yes and no votes in the House. To capture the interest of each member's constituency on foreign assistance, the regression analysis includes two indicators that predict the interests of a particular congressional district in foreign aid: the percent of the population that is foreign born (by *state*), and the outcomes of the most recent presidential election (by district). These measures, incorporated into the regression, capture constituency interest in foreign matters and overall constituency ideology, respectively. In an effort to examine the importance of the executive branch position in foreign aid voting, *Congressional Quarterly*'s presidential support scores (index values for the frequency of support for presidential positions) were coded at the ratio level and incorporated them into the regression analysis, noting whether members with a history of support for a given president would follow that pattern in their vote on aid appropriation. As a final possible independent variable, the length of tenure for individual members was examined under the assumption that members with longer tenure are more secure in their reelection and therefore more free to vote on the basis of ideology.

Overall trends in the relationships between the independent and the dependent variables were examined using crosstabulation in most cases. Cramer's V was employed as the measure of association for the asymmetrical tables where ideology was the independent variable. Phi was used as the statistical measure of association in the case of the square tables where party affiliation was the independent variable. Pearson's Chi-square was used in all cases to test statistical significance at the .05 level. To eliminate some of the shortcomings of crosstabulation, t-tests were also performed using the ratio level data for ADA score. The heart of this study's investigation, however, is contained in the logistic regression analysis. Regression was selected as the method for the analysis because it allowed each of the possible independent variables to be

BEST COPY AVAILABLE

incorporated, and it indicated the relative importance of each factor in influencing members' voting decisions. Each regression included the ADA score, party, region, tenure, district presidential vote, district foreign-born percentage, and presidential support indicators. The results from the regression runs for each of the nine votes have been analyzed to provide an applicable interpretation of each variable's impact on voting decisions. It is important to note that *only* the variables that were significant at the .05 level were analyzed for each Congress; however, all variables, regardless of significance, were included in the overall equations. Since some votes included many more significant variables than others, the five votes chosen for in-depth analysis (FY1989, FY1990, FY1993, FY1994, and FY1996) had the greatest number of significant variables.

Logit outputs pose some difficulty for clear, accurate interpretation, and a method was used in this study that allows logit to predict the probability that a given congressman will vote "yes" on aid legislation. Four cases that were particularly typical of the liberal Democrat, conservative Republican, moderate Democrat, and moderate Republican, were selected from the data set (chosen specifically for their "typicalness"), and probabilities for yes votes were determined for the five votes with the most significant variables (one vote from each Congress represented in the study). To achieve a basis for comparison across the five Congresses, the values for the same four model members were used to analyze a vote from each Congress.

BIVARIATE ANALYSIS

Crosstabulation and t-test methods were used to obtain an overall picture of the relationships between party and vote, ideology (in five categories) and vote, and region and vote. Although space considerations prevent detailed discussion and presentation of the data here, the general conclusions are worthy of note. The crosstabulations of ADA score and vote seem to suggest a pattern of ideological voting behavior on foreign aid appropriations bills from FY1989-FY1995. Although foreign aid was almost always supported by a majority of members from all locations on the ideological spectrum, ideology served as a reasonably accurate predictor of voting on aid appropriation. In each vote from FY1989-FY1995, the most conservative members were most likely to vote no in significant numbers, while liberals consistently voted most strongly for foreign aid. The measures of association for these years reflect the fact that higher ADA scores (indicating greater liberalism) are a good predictor of vote on foreign aid--when the relationship is examined without regard to other possible influences. Since the crosstabulation method used ADA score value categories (ordinal level) and therefore provided less accuracy than is desirable, t-tests were also performed on members' ADA scores at the ratio level. The t-tests allowed the bivariate relationship between ideology and vote to be explored further. Overall, the results of the t-tests confirmed the pattern of ideological voting suggested by the crosstabs. Members voting against aid were more conservative than members who voted for aid--at least through the FY1995 vote. (As a side note, crosstabulation between ideology and *party* yielded a very strong correlation between the two independent variables--Cramer's V was .71 ($p < .001$) for the aggregate correlation.)

When party is crosstabulated as an independent variable with individual votes as dependent variables, a pattern similar to that of ideology emerges, although the party tables contain weaker associations. On the bills from FY1989 through FY1995 (with the possible exception of FY1990), Democratic affiliation was a weak to moderate predictor of vote. Members with GOP affiliation were more likely than Democrats to vote no, approximately 30% of the Republican party consistently voted against aid appropriations. The pattern completely reversed for FY1996, contradicting the original hypothesis, as discussed above. And, as was the case with the ideology crosstabs, no pattern or relationship between party and vote emerged in the FY1997 vote. Similarly, in the region crosstabs, the apparent voting pattern is relatively clear up to the FY1997 vote. Members from the northeastern states voted consistently for foreign aid appropriations, with only a handful of defectors for each vote. In the midwest, at least three-quarters of members generally favored foreign aid, in fact, the percentage of midwestern members voting against the appropriation bill was usually similar to the percentage of House members in opposition. Western members voted similarly to the whole House in some years, but on several votes--notably FY1994-FY1997--westerners posed greater opposition to aid appropriations. Southerners, while generally providing a majority of their votes for foreign aid, did display a strong and consistent opposition to aid appropriations through FY1996. The regional pattern vanished for the FY1997 appropriation, in which over 80% of representatives from each region supported aid, suggesting that region no longer served as even a weak predictor of how members vote on foreign aid.

Overall, region seems to be functioning as a surrogate for ideological and party differences, as the logit discussion will demonstrate.

LOGIT REGRESSION ANALYSIS

The results of the logit analysis described in the Methods section, while simplified, are perhaps the most clear of the bivariate and multivariate analysis. The very liberal Democrat member showed an extremely high probability of voting yes on foreign aid in all five years, the probability of supporting aid never fell below .97 for the most liberal Democrat. In addition, the voting trend for the liberal member is quite consistent across the five Congresses. The results for the very conservative Republican case are nearly as consistent and conclusive. The conservative's probability of voting for foreign aid hovered around .25 for the five votes, although the probability increased somewhat to .35 for the FY1996 vote. This shift is in accord with the trends observed in the bivariate data for more conservatives to vote for the reconfigured aid appropriation.

Table 1. Probabilities of Yes Votes on Foreign Aid Appropriations
(Based on Logit Regression Analysis)

Member Type	Congress 100th	101st	102d	103d	104th
Liberal Democrat	.99	.99	.99	.97	98
Moderate Democrat	.81	.82	.76	.37	.79
Moderate Republican	.60	95	.66	.69	61
Conserv. Republican	.26	26	.19	.22	35

The moderate Democrat case produced a less consistent pattern of voting, but one that nonetheless strongly suggests a trend for ideologically middle-of-the-road Democrats. Probabilities for the moderate Democrat archetype were around .80 for the FY1989, FY1990, FY1993, and FY1996 votes. Surprisingly, one of the five years shows a notable inconsistency with this pattern--the moderate Democrat had only a .37 probability of voting yes on the FY1994 appropriation, although the probability returned to the .79 level for the FY1996 vote.

The pattern for the moderate Republican archetype displayed a similarly unusual inconsistency in one vote. Overall, the moderate Republican demonstrated about a .60 probability of a yes vote, but in the FY1990 vote, the same congressman had a .95 probability of favoring aid. It seems unusual that moderate Republicans should, for just one vote, exceed the moderate Democrats and approach the liberal Democrats in their likelihood to support aid appropriations.

Despite the two inconsistencies, a pattern that supports the initial hypothesis of this study emerges from the representative case analysis. Liberal Democrats showed very strong support for aid, while conservative Republicans were notable for their low support. The moderates appear to have been influenced by their partisan affiliations--Democrat moderates showed higher levels of support than Republicans of similar ideological persuasion. Explanations for the inconsistency in the trend among moderates may lie in the international situation surrounding the anomalous votes. 1989, when the FY1990 vote was taken, was a heady year for America in the international arena as the Iron Curtain began to show signs of serious weakness. The usually more skeptical Republicans may have been persuaded by the international atmosphere of 1989 to vote for aid. The drop in moderate Democratic support in 1993 is much less easily explained. In fact, one might expect the moderate Democrats to *increase* in likelihood of support in 1993, the first year in the study in which a Democrat held the White House. The puzzling discrepancies should not detract, however, from the overall picture of voting behavior provided by the representative case analysis, especially among the most liberal and most conservative House members.

CONCLUSIONS

The central hypothesis of this study was that ideology and party are the most powerful predictors of House foreign aid voting. The hypothesis posited that more liberal, Democratic members are more likely to vote for aid than their conservative, Republican counterparts. In addition, the central premise included the supposition that House foreign aid voting has become more ideological and partisan since 1989--especially since the 1994 Republican "revolution" in the House. The bivariate and logit roll-call analysis of the nine votes has provided broad support for the assumption that ideology and party are important influences on voting behavior, however, the data fail to support the assumption that ideology and party are the *primary* factors in aid voting decisions. Clearly, the probabilities derived from the logit outputs do not suggest that ideology explains voting completely, and the logit outputs themselves assign high importance to other variables, including executive support scores and tenure. The analysis also fails to support the notion that the voting has become *increasingly* ideological and partisan. In fact, the bivariate analysis in particular suggests that the trend in voting behavior from FY1989 through FY1995 underwent significant (but unclear) changes in the FY1996 and FY1997 votes. It seems logical that conservatives would become more likely to vote for aid in FY1996 and FY1997 because, as was mentioned in the Introduction, the Republicans in Congress revised aid priorities and cutback overall appropriations to suit more conservative views on foreign affairs.

The "representative cases" analysis of the logit model provides the most concise and conclusive interpretation of member's voting decisions. The effect of ideology and party presents itself *only when the analysis considers all of the other factors usually associated with members of a particular ideological and partisan persuasion.* When four members who represent the typical conservative Republican, moderate Republican, moderate Democrat, and liberal Democrat are studied across the five Congresses, the probabilities that each will vote for aid appropriations corresponds quite well to the initial hypothesis that liberal Democrats are more likely to vote for aid than conservative Republicans. This study, then, failed to demonstrate that members vote unidimensionally on foreign aid; it also did not reveal a multidimensional model of voting in which ideology and party are the clearly predominant factors. Instead, the data suggest that members do vote roughly along ideological and party lines when the other factors--especially executive support, tenure, and constituency characteristics--are set at values that are common to members of their ideological and partisan persuasion.

The conclusions of this study fit neatly into the existing body of research. Although the results suggest an important role for ideology, they cannot be construed to coincide with Schneider's findings that ideology is the only salient influence on foreign affairs voting. Rather, they fit into the multidimensionalist and policy-specific paradigms by finding that a variety of influences, including party and ideology, influence voting behavior on foreign aid appropriations in the House of Representatives.

A Quantitative Study of the Essence of Federalism: Who Does it Benefit:

Kim Odoms

Department of History and Government
Bowie State University
Bowie, Maryland 20715

Faculty Advisor:

Dr. Abdul Karim Bangura

This research examines whether there is a relation between federal funding and its residual effects on state institutions, programs, and their spending practices. Additionally, this study seeks to determine if the amount of federal funds to individual States is driven by modern federalism. The data collected for this study provides information regarding the issues of federal funding and its impact on federalism. The empirical findings from this research suggest a significant correlation between federal funding to States and modern federalism.

INTRODUCTION

Federalism has grown into a controversial issue among politically active Americans. Traditionally, conservatives advocate big business and are against federal regulation. Conservatives refute national policies that focus on labor and consumer issues. If it were politically feasible, conservatives would prefer funding without the restraints of regulation. Contrarily, liberals advocate national policy and are against regulations that cater to big business issues. Ideally, liberals' views reflect a society where power is balanced between the states and the federal government. Elaborately, neutral positions are concerned with "(1) decentralized federal field offices; (2) interstate compacts and commissions; (3) rule-making at the federal level, but enforcement at the state level; (4) federal regulation of new facilities, but state regulation for old facilities; and (5) federal policy for air pollution, but state policy for water pollution" (Nagel 1996:499). Subsequently, American ideologies determine their political affiliations.

New Federalism has allowed states to escalate to a "substantial equivalency status" having similar legal authority as many federal agencies to investigate and conciliate complaints, and enforce laws in a federal capacity at the state level. Ultimately, federalism's opponents fear that policy goals are more vulnerable to subversion by state regulated agencies. In other words, opponents fear that shifting enforcement responsibility is the first step of many to irradicate public policies by chipping away at the exterior so that it provides a loop hole to annihilate the core or essence of many public policies. Shifting responsibility may be a clever "political smoke screen" to pursue a more poignant objective (Nagel 1996:506)

Since previous studies on modern federalism (e.g., Hornbostel 1973, Nelson 1982, Barro 1983, Fisher 1987, Dumenil 1990, and McDowell 1995) focused exclusively on the merits of the policy, the main objective of this study is to determine if the flow of federal funds to the states has caused an increase in the number of state employees. In essence this study seeks to examine whether there is a relationship between federal funding and its residual effects on state institutions and programs and their spending practices. This objective is important because the correlation may reflect a bias in the allocation of funds. Clearly, the allocation of federal funds has a direct impact on the diversity and sophistication of technology that is available to states. Therefore, states that receive the most funding are likely to be more prosperous.

In determining the nature of allocation of federal funds to states, two main questions need to be answered: (1) Is there a correlation between funds allocated by the federal government and the number of state employees? (2) If so, do the data infer an increase in the number of state employees?

RESEARCH METHODOLOGY

Using a quantitative methodological approach, the following theoretical framework is designed to graphically identify the two main factors that were independently and dependently manipulated for this research. Scientifically, the independent variable, the flow of federal funding, is the basis for measuring how the dependent variable, the increase in the number of state employees, affects or influences the increase of the number of state employees. Thus, the theoretical framework is represented accordingly:

The Flow of Federal Funding to States		Increase of State Employees
(Independent Variable)	→	(Dependent Variable)

Basically, the assumption is that there is a relationship between an increase of state employees and the amount of federal funding to states. Consequently, the Hypothesis for this study is H_1: If the flow of federal funds to states increases, then the hiring of state employees will increase.

The Simple-Time Series design is the most appropriate design for this study. Diagrammatically, the X represents the flow of federal funds to states; O represents the observation of the number of state employees. This particular design is used to determine whether the distribution of federal funds is responsible for an increase in the number of state employees over time. Subsequently, this design provides the researcher with the necessary basis to adequately collect and analyze the necessary data.

$$X \; O_{1981} \ldots O_{1994}$$

In an effort to accurately conduct this research on a macro level of the entire United States, the convenient sample appeared to be the most feasible means of representation since the data were available. The data were collected from the Census Bureau. The data collection technique chosen was document analysis. The bases for choosing this method included convenience, availability, and feasibility.

DATA ANALYSIS

The data collected were analyzed in two stages: the univariate and bivariate. The statistical package used to conduct this analysis is GB-STAT. Two types of statistics are used for analyzing the data at the univariate stage: the mean and the standard deviation. The results generated form the computer runs for these statistics are presented in Table 1.

TABLE 1: Mean and Standard Deviation of Variables

Variable	Mean	Sample Standard Deviation	Sample Variance	Coefficient of Variation
STAT	1.41	941922.70	8.87	.06
FEDR	125398.70	23172.87	5.36	.18

where:

STAT = number of State employees
FEDR = amount of federal funding to States

Table 1 shows that the average number employees hired per year by the States between 1981 and 1994 is 1.4 billion; the standard deviation from year to year is 941,923. Thus, the variance over time for this variable is not statistically significant at the .05 level. The average amount of federal funding for the states from 1981 to 1994 is $125 million; the standard deviation from year to year is $23 million. Also, the variance for this variable over time is not statistically significant at the .05 level. Subsequently, the sample variance reveals degrees of freedom that measure about 9 for state employees and 5 for federal funding.

Simple correlation and simple regression procedures were used to analyze the data for the bivariate level. Correlation measures the strength of the relationship between the independent variable (federal funding) and dependent variable (increase of state employees); regression measures the direction or the nature of the relationship between the variables. The results generated for these techniques after the computer runs are summarized in Tables 2 and 3.

TABLE 2: Correlation Matrix

	FEDR
STAT	.99052**
**P<.01	*p<.05

From Table 2, It can be seen that STAT significantly correlates with FEDR at the .01 level with a correlation coefficient of .99. Therefore, there is a positive and statistically significant correlation between the number of State employees and federal funding allocated to states between 1981 and 1994.

TABLE 3: Current Regression Summary Table

Dependent Variable = STAT
Standard Deviation Error Estimate = 135695.3
F = 520.0219
(ALPHA) Constant 9138860

Independent Variable	B-Coefficient	Standard Deviation Error (B)	T-Value	Probability
FEDR	40.26238	1.765585	22.80399	<.001

Table 3 shows that the independent and dependent variables have a statistically significant relationship at the .01 level (T-Value = 22.80). Thus, the hypothesis tested in this study, H_1: If the flow of federal funds to states increases, then the hiring of state employees will increase, is accepted.

CONCLUSION

The accepted hypothesis that federal funding allocated for states increases the number of state employees indicates that federal funding has consistently, from 1981 to 1994, helped to place otherwise unemployed citizens in jobs created by states. Although this research reveals a statistically significant relationship, federal funding may not be the sole source for an increase in the number of state employees. Therefore, other researchers may consider exploring other significant variables. A potential researcher might consider examining state hiring practices, various training and follow-up programs, marketing procedures, or other techniques used in state hiring procedures.

On the surface, federal funding and the increase of modern federalism appears harmless; yet, after examining the underlying issues of some social policies it is apparent that politicians at the state level have the propensity to abuse or cloud the initial purpose of federally implemented policies and regulations. Additionally, major political actors have the propensity to inadvertently change the goals of original laws by shifting enforcement responsibilities. Theoretically, shifting responsibilities may perpetuate shifting federal aid from places (state institutions) to people (state leaders).

Since the signing of the Declaration of Independence and the subsequent indoctrination of the Constitution of the United States, there has been an ongoing tug of war for sovereignty between the federal government and states. Conversely, States have fought to obtain an independent existence, yet they have fought to increase government funding for state institutions. Basically, states have criticized the federal government for encroaching their independent and economic growth. Nevertheless, states have also complained that the government funding they do receive is not enough to make a notable difference. Realistically, perfect relationships do not exist. Obviously, the national and state interdependent relationship is not the exception to the rule. Perhaps, federalism presupposes a harmonious relationship properly channeled through the roots of reciprocity.

Clearly, the systems analysis framework is lacking an equally divisive tool to further examine the concrete subsystems. Thus, concrete analyses would provide political scientists with an in-depth examination of the often overlooked subsystems. Perhaps, a closer examination of subsystems would provide a strong preliminary foundation and formative analysis to further examine modern federalism.

The Concepts of Community and Individualism in Twentieth-Century Presidential Nomination Acceptance Speeches and Inaugural Addresses

Stephen V. Potenza

Department of Political Science
Union College
Schenectady, NY 12308

Faculty Advisor:

James E. Underwood

Beginning in the early 20th century, the institution of the American presidency underwent a fundamental reinterpretation by the both the occupants of the office and the American public. Since that reinterpretation, public expectations of the president's role in government have been raised; and electronic communication has become a means by which presidents communicate directly with the public in attempting to fulfill those roles. Recent scholarly research has examined these changes in the presidency and the increased importance of presidential speech in American politics. This thesis, however, specifically examines the use of the concepts of community and individualism by presidents and candidates in their nomination acceptance speeches and inaugural addresses between 1904 and 1997. This thesis argues that the concepts of community and individualism as they appear in the liberal and republican traditions of early American political thought also appear in the rhetoric of presidents and candidates during the twentieth-century as they define the "public good" on the ceremonial occasions of their nomination acceptances and inaugurations.

THE INSTITUTION OF THE PRESIDENCY AND PRESIDENTIAL RHETORIC

While the United States Constitution requires only one communication from the President each year, the evolution of the office of the presidency, especially in the latter half of the twentieth century, has been such that presidential rhetoric is now not only frequent but central to the duties of the executive office. In fact, once reserved for special occasions or crises, presidential speechmaking increased by almost 500% between 1945 and 1975 (Zernicke, 1994).

Accompanying, or perhaps stemming from, this increase in presidential speechmaking during the twentieth-century has been a re-conceptualization of the institution of the presidency in which rhetoric figures prominently. Since Richard Neustadt argued in 1960 that presidential power is the power to persuade his various constituencies, many political scientists have explored the relationship of rhetoric to the presidency. The subject of the first chapter of the thesis, therefore, is a brief review of some components of this re-conceptualization. Jeffrey Tulis argues in *The Rhetorical Presidency* that the modern presidency draws authority from two "constitutions," the original Constitution and a new "constitution" comprising, in Tulis words, "contemporary presidential and public understanding of the constitutional system and the president's place in it" (Tulis, 1987). Paul Zernicke, drawing on the work of Clinton Rossiter, similarly argues that a changing understanding of the presidency has resulted in increased importance of presidential rhetoric, for the roles a modern president is expected to play are so numerous and the obstacles he encounters so great that speaking to the public is all a president can do to build support for the ideas that will allow him to fulfill those roles (Zernicke, 1994). Finally, Mary Stuckey offers the advent of television and its increasing importance in American society as another explanation for the frequency of modern presidential rhetoric (Stuckey, 1991). The work of some scholars on rhetorical techniques used by presidents and on different genres of presidential speech is also reviewed.

A THEORETICAL FRAMEWORK

Michael Kammen argues in *People of Paradox: An Inquiry into the Origins of American Civilization* that "the push-pull of both wanting to belong and seeking to be free has been the ambivalent condition of life in America, the nurture of a contrapuntal civilization" (Kammen, 1973). In fact, according to Daniel T. Rodgers, government itself in America is based on competing notions of individualism and community as expressed in the two world views of liberalism and republicanism. For liberalism is that individualistic, Lockean frame that sees the world in the private terms of the private self, private property, and a wealth of private accumulation held together by the competitive market. Republicanism, on the other hand, is that frame that sees the world in the public terms of the public good, a distrust of the market, self-restraint, and a commitment to "the commonweal of men called 'virtue'" (Rodgers, 1987).

The second chapter of the thesis comprises a synthesis of Kammen's and others' theories of community and individualism in America with the late-eighteenth and early-nineteenth-century philosophies of liberalism and republicanism into a theoretical framework useful in understanding the speeches studied in the third, and final, chapter. Nomination acceptance speeches and inaugurals addresses are different genres of presidential speech with important similarities, for they are set apart from other genres in that they are ceremonial speeches. Acceptance speeches, as Ritter writes, are "merely a ceremony of acceptance that occurs after the serious work of the convention has concluded," and as Jamieson and Campbell note, inaugural addresses are a ceremony accompanying presidential investiture (Ritter, 1980; Campbell and Jamieson, 1990). Being epideictic, or ceremonial speeches, acceptance speeches and inaugural addresses are a form of rhetoric that praises or blames, invites the audience to evaluate the speaker's performance, recalls the past and speculates about the future. Presidents and candidates achieve these ends in ceremonial addresses by offering for contemplation to their audience a philosophy of government and society, relating to the present both evaluations of the past and visions of the future, and praising the institution of the presidency and the values and form of government of which it is a part (Campbell and Jamieson, 1990). As Ritter suggests, moreover, these speeches function as political jeremiads, for through them presidents and candidates warn the American public that they have deviated from the fundamental principles undergirding the "America dream" and that a return to the national values on which the country was founded is needed to ensure the future security and prosperity of the country. "National values," often defined in terms of community and individualism, are the answer to that question of how to define the "public good" that has so often been answered in ceremonial addresses.

Furthermore, these "national values" reflect what Kammen describes as the biformity in American culture, a conjunction of two concepts without losing the meaning of either concept, encompassing the competing republican and liberal philosophies of the late-eighteenth and early-nineteenth-centuries. It is this biformity that informs presidential use of the concepts of community and individualism in the speeches studied. In fact, the Jeffersonian synthesis of the liberal principles of self-reliance, the cultivation of self-discipline, and cooperation with the republican notions of duty and virtue is an early instance of this biformity in American political thought; and the notions of affective individualism and self-less virtue resulting from this synthesis appear in the nomination acceptance speeches and inaugural addresses of twentieth century presidents and candidates for the presidency.

The language of the speeches examined in this thesis thus contains conceptions of community in what Michael Sandel has called the instrumental, sentimental, and constitutive senses as these conceptions appeared in American culture in the ideas of the liberal tradition in the case of the first two conceptions and the ideas of the republican tradition in the case of the third (Sandel, 1982). Speakers using language indicative of the instrumental or sentimental conceptions assume that the public good arises, as Jefferson stated, from "each individual seeking his own good in his own way" (Curry, 1991). But the sentimental conception differs from the instrumental conception in its view of what comprises that individual good, for the sentimental conception views cooperation as an end in itself while the instrumental conception views such cooperation only as a means to private ends. Both conceptions, however, view self-interest to be the glue holding together communities.

The constitutive conception, however, is not absent from the rhetoric of presidents and candidates on these ceremonial occasions although it does appear far less often than the instrumental and sentimental conceptions. That is, presidents and candidates sometimes depart from their emphasis on the pursuit of individual self-interest to admonish their listeners not to forget the republican virtues of duty, sacrifice, and "love of country." Thus alongside liberal notions of community as the sum of individual pursuit of self-interest there survives in ceremonial rhetoric the republican notion "that what made republics great or ultimately destroyed them was not force of arms, but the character and the spirit of the people" (Shalhope, 1972). In the constitutive conception, men are conceived to be not only egoistic beings but social beings who will pursue ends for the community even if self-interest must be sacrificed in so doing.

CONCLUSION

Having so developed a framework with which to examine the speeches, what conclusions can be drawn from this study of ceremonial rhetoric? The "public good" has largely been defined during the twentieth century in terms of the instrumental and sentimental conceptions of community indicative of the influence of the liberal tradition developed during the latter part of the eighteenth-century. Of the men included in the text of the thesis, fourteen of eighteen exhibit instrumental and sentimental language; these men argue that the interests of the individual are the basis of the national community. Yet the constitutive conception, that conception of community conceiving community to be a part of human nature, appears in the speeches of three men.

One might want to explain this emphasis on the individual in presidential speech as a result of the ascendancy of liberalism over republicanism in the early part of the nineteenth-century; however, a better explanation for this apparent predominance of individualism may be that at least on the two ceremonial occasions considered in this study, the speeches of the presidents examined in this thesis suggest the prevalence of that biformity encompassing both the liberal and republican traditions identified by Kammen. In fact, the appearance of the instrumental, sentimental, and constitutive conceptions of community evidenced by the speeches suggests that Ralph Barton Perry was correct in asserting that "American self-reliance is a plural, collective, self-reliance -- not 'I can' but 'we can'."

Presidents and candidates whose speeches contain appearances of the instrumental and the sentimental conceptions of community speak the language of the individual, and their speeches are replete with references to opportunity and responsibility. When Roosevelt and Reagan, for example, argue that opportunity must be secured for individual Americans, they call on the responsibility of government and voluntary associations respectively. Other speeches contain similar entreaties to collective self-reliance; only through the help of others can the individual reach fulfill his potential in these conceptions.

Appeals, of course, are made to the collective spirit in the few speeches in which appear constitutive conceptions of community as well. Although the language of these speeches includes calls to the "virtuous citizen" of republicanism, it is nevertheless a language similar in some ways to that of the other conceptions. The calls to service by Harding, Stevenson, and Kennedy parallel the calls to responsibility made by Roosevelt, Reagan, and others; and "cooperation" is, in fact, a word used in the language of all three conceptions. In the American biformity, the two major traditions of political thought from the founding era, liberalism and republicanism, are conjoined.

This thesis concludes, therefore, that despite the changes that presidential speechmaking has undergone in the past century, one constant has been the appearance and use of the concepts of community and individualism in the ceremonial rhetoric occasioning nomination acceptances and inaugurations. For as the situation of America has changed from election to election and president to president, the liberal and republican traditions that are the foundation of the American political system endure in the speeches. Whether in time of economic depression, prosperity, peace, or, war, those who hold and those who seek the office of the presidency reach for the familiar instrumental, sentimental, and constitutive conceptions of community when they address the nation. They implore their audiences to recall the past, evaluate the present, and look to the future; and they do this not with the incessant "I can" so typically heard in twentieth-century, but "we can."

A Comparative Study of the Levels of Political Socialization of Children in Two New Hampshire Towns.

Kathleen M. Ridolfo

Political Science
University of New Hampshire
Horton Social Science Center
Durham, NH 03824

Faculty Advisor:

Clark Hubbard

Political socialization is the process by which children become aware of politically relevant attitudes and behaviors. Without this socialization, any given political system would continuously become obsolete and be replaced by a new system with each new generation of citizens. In order to prevent the collapse of the political system, every system must offer its young members ways in which to identify with and form an allegiance to the system.

BACKGROUND

The importance of the process of political socialization becomes evident when we note that many political issues involve rules about the exercise of authority. One assumption of political socialization theory is that people tend to seek congruence between their own personal authority experience and their relationship to broader political authority. (Weissberg, 1974) A child's experience with authorities (parents, police, and court officials) has an impact on their political attitudes, especially in different social classes. Negative experience with minor authority figures could lead to a negative attitude towards broader political authority (the government) in adulthood. With maturity and increased political sophistication, new information and experiences modify, but do not replace earlier socialization. (Weissberg, 1974) Since the regime is a fundamental element in all political systems, it is of value to learn if members of society continue through generations to offer sufficient support to the structure of political authority. (Easton and Dennis, 1969) Without a structure of political authority, no political system could endure for long. Every political system is subject to various kinds of stress that threaten to prevent a society from continuing to allocate values authoritatively. Socialization is interpreted as one kind of response through which political systems may be able to ward off certain kinds of stress on the structure of political authority.

Numerous studies in the field of political socialization were conducted from the late 1950s to the early 1970s. Overwhelming evidence points to the fact that children from a very young age have developed ideas about the government and political system. Children can pick up informal political learning subconsciously, it appears, from socialization agents like school, parents, friends, television, media, as well as participation in associations which teach civic responsibility.

In their 1961 study on children, Easton and Dennis outlined four factors through which the child comes to an understanding of membership in the political system. These factors are politicization, personalization, idealization and institutionalization. By measuring responses to questions surrounding these factors, one can discern stages of development in the socialization process, through the measurement of diffuse support, benevolence towards leaders, and awareness of the differences between the public and private spheres.

DATA AND METHODS

Subjects

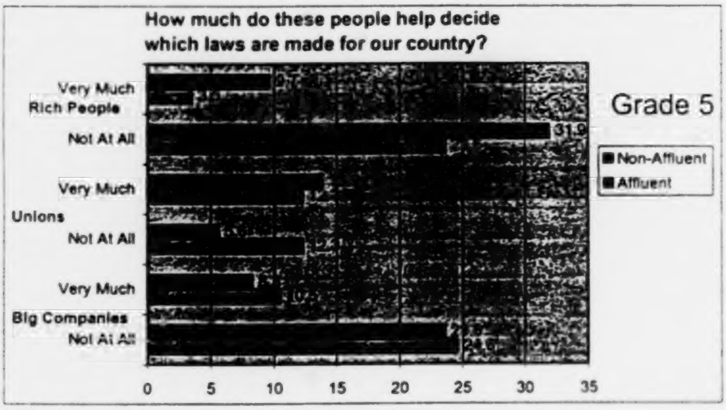
The purpose of the study was to determine if American children today are being trained for future citizenship in a manner, which provides for the continuance of our system of government. Specifically, do children from affluent and non-affluent communities receive the same training for citizenship? Do they possess the same sentiments towards authority figures? The study examined variations in political socialization between younger and older children in an affluent and a non-affluent community. The communities were chosen based on data provided by the New Hampshire Department of Resources and Economic Development. Communities were chosen based on school district size, median income levels, the number of single parent households, and in the case of the non-affluent community, the number of children living below the poverty line. Because researchers agree that the truly formative years of the maturing member of a political system would be the years between three and thirteen, children from three different age groups were surveyed. Three hundred seventy students participated in this study; one hundred ninety two students from an affluent community and one hundred seventy eight students from a non-affluent community.

Design and Procedure

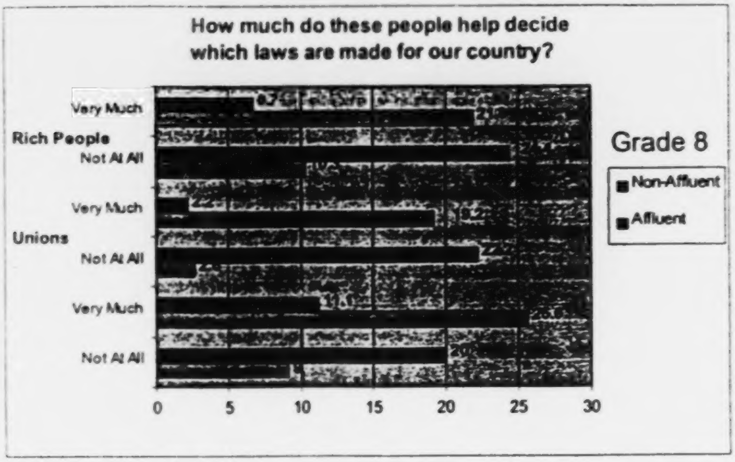
Paper and pencil surveys were administered to children in the second, fifth and eighth grades between May and December, 1996 (the grades being adjusted to third, sixth and ninth grades for the fall term.) Questions from previously administered surveys were used. (see Easton and Dennis) The survey was read aloud to the youngest group by myself, while the older groups worked alone with any questions being answered by an administrator, either a teacher or myself.

RESULTS

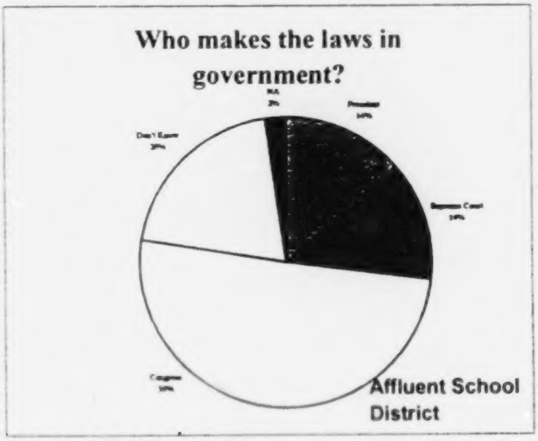
Students from the affluent community displayed a greater awareness of political actors and a more realistic view of government. This was evident in their responses to questions measuring benevolence, cognitive development, knowledge and dependability ratings of authority figures. Children from the non-affluent community were less politically mature. However, non-affluent students scored the same for better than affluent students on questions pertaining to general knowledge (Who is the governor of NH?). But, they scored significantly lower than their same age mates on questions pertaining to the roles of political actors (How much do these people help decide which laws are made for our country?). The results suggest that for the affluent students, advantages in these areas are likely to lead to greater efficacy and participation in adulthood.



BEST COPY AVAILABLE

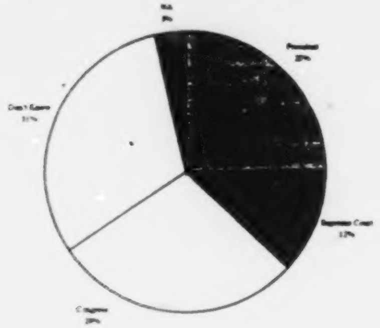


Results also suggest that affluent children are more willing to participate in the political process. On questions pertaining to knowledge (Who makes the laws in government?) non-affluent children were likely to pick "I don't know" or not answer when uncertain, while affluent children were more likely to choose a person or institution. It appears that affluent children feel more comfortable and "knowledgeable" (even if they're not) in the discussion of politics.



BEST COPY AVAILABLE

Who makes the laws in government?



Non-Affluent School District

The study did not pinpoint particular social agents as having a specific impact on children in each community, rather differences in social circumstances between the two communities. It is likely that the disparities in education curriculum, levels of parental participation in the political process, extracurricular activities and media exposure all impact the child's socialization to the political arena. These factors taken together suggest that in terms of citizenship, the disparities between affluent and non-affluent children are likely to persist into adulthood.

A Qualitative Study of Minority-Majority African-American Congressional Districts and African-American Representation in Congress

Marvin M. Silver

Department of History and Government
Bowie State University
Bowie, Maryland 20715

Faculty Advisor:
Dr. Abdul Karim Bangura

This study provides a systematic analysis of the recent redistricting of a majority of the African-American electoral districts in the South and the efficacy of minority representation in the United States Congress. Using a qualitative/simple case study, the non-numerical data collected for this study cover the socio-economic status of the recent redistricted minority-majority African-American congressional districts and the African-American representatives of those districts. The Correspondence Theory of Representation is used as a guide to test the efficacy of each district and its representative. The substantive findings derived from the data analysis suggest that the major propositions examined could not be definitively determined in this study.

INTRODUCTION

The history of redistricting in twentieth century America is well known, and the frequently used practice of redistricting is gerrymandering. Gerrymandering is the manipulation of districts lines for political advantage. Racial Gerrymandering is the manipulation of district lines to enhance or reduce the representation of particular racial groups. The increases in African-American representation in Congress have resulted from racial gerrymandering, the Voting Rights Act of 1965, and the decision of the Supreme Court to enter the political thicket of redistricting. The reasoning for drawing congressional districts to ensure the descriptive representation of African-Americans (minority-majority districts) is openness to African-Americans, and the ability of African-Americans to elect the representatives of their choice who will best address their concerns. Today, changes in redistricting and African-American representation have been very much a function of key court decisions (see for example, Congressional Quarterly Weekly Report, vol.53, no.26, 1996:1944-9).

Thus, employing the Correspondence Theory of Representation as a guide, this study seeks to provide a systematic analysis of the recent redistricting of a majority of the African-American electoral districts in the South and the efficacy of minority representation in the United States Congress. The significance of this study hinges on the fact that pertinent works on the subject are case studies that focus on the threat that redistricting has on minority representation and the constitutionality of racial gerrymanders (Erenhalt 1983, Cohodas 1994, O'Connor and Souter 1994, Raskin 1995, Gruewald 1995, Tabin 1995, Idelson 1995, and Berstein 1996). These studies are greatly opinionated and atheoretical.

THEORETICAL FRAMEWORK

The theory that guides this study is the Correspondence Theory of Representation. This theory emerged in response to the questioning of effective representation. The problem is that even though a representative is able to act as a voice of his/her constituency, he/she could be accused of being unrepresentative on other grounds. This is because most representatives do not share the same social or cultural background of their districts. For instance, most representatives are middle- or upper-class professionals, lawyers, majority male, older than members of their constituencies, and well educated. The best particular phrase that represents the legislature of the United States is "White Anglo-Saxon Protestants" (WASPS) (Bangura 1996:43).

In addition, there are five types of representation that reflect interactions among the central state organs, lower government agencies, and social groups, and they are as follows: Monopolistic, Centralized, Coordinated, Specialized, and Comprehensive. Monopolistic representation refers to the case of a powerful representative who monopolizes the decision-making process, denying lower government agencies and social groups the right to make policies (Bangura 1996:45). Centralized representation exist when representatives in the national government gain dominance over representatives of local political units, such as village assemblies, town council, municipal governments, and provincial administrators (Bangura 1996:45). Coordinated representation refers to a situation where representatives of a single agency formally orchestrate the functional activities of government (Bangura 1996:46). Specialized representation can be found in cases where representatives become both differentiated (specialized) and independent (Bangura 1996:46). Comprehensive representation exists particularly in industrialized societies in which representatives exercise a wide scope of power; that is, they perform a comprehensive variety of activities: system maintenance, construction of an economic infrastructure, and provision of social services to individuals (Bangura 1996:47). This is the type of representation that is performed in these minority-majority congressional districts.

So, the best alternative to answer this problem lies in having a government that corresponds to the characteristics of the state (proportional representation). Since this study examines the United States, let us use it for an example. The United States population is made up of more than just WASPS. It consists of not only males, but also females; not only whites, but also blacks; not only Protestants, but also Catholics and others. The United States is a country of immigrants that represent almost every culture, religion, and race in the world. So, the proposed government in the United States must represent all citizens in proportion to their numbers in the population.

Thus, the formal position taken in this study is that the recent redistricting of minority-majority congressional districts in the South will have an adverse effect on minority representation in Congress. So, the major propositions proffered in this study are the following:

> P1: If all minority-majority congressional districts are considered unconstitutional, then this will have an adverse effect on minority representation in Congress.

P2: If the redistricting of minority-majority congressional districts
increases, then
the democratic stronghold of minority partisanship will dilute.

Given the preceding propositions, the Correspondence Theory of Representation is employed. This is to facilitate a systematic analysis of the available data on gerrymander.

ANALYSIS

After identifying the social makeup of each district that was affected by gerrymandering and the Congressmen/women who represented those districts (see the Congressional Black Caucus of the 104th Congress report of 1995), it became feasible to determine the type of representation which existed in those districts, and to apply the Correspondence Theory of Representation. As stated earlier, there are five types of representation that reflect interactions among the central state organs, lower government agencies, and social groups, and they are as follows: Monopolistic, Centralized, Coordinated, Specialized, and Comprehensive. The one that most characterizes the type of representation in each African-American majority congressional district is Comprehensive representation. This type of representation exists particularly in industrialized societies in which representatives exercise a wide scope of power; that is, they perform a comprehensive variety of activities: system maintenance, construction of an economic infrastructure, and provision of social services to individuals (Bangura 1996:47). It is apparent in each African-American majority congressional district that each congressman/woman performs a comprehensive variety of activities. It is also true that each African-American representative of those districts addresses issues of African-American concern, but their primary concern is that of their constituents. This is shown in their success to effectively address the concerns of their constituents by acting as the voice of those constituents and by securing funds and appropriations to those districts. Their success also refutes the philosophical premise that only minorities benefit from minority-dominant voting districts.

This leads us to the issue of how effective is the Correspondence Theory of Representation in testing these African-American majority congressional districts. It is very effective; however, there are some limitations. To iterate what was stated in the theoretical framework, this theory emerged in response to the fact that even if a representative were able to act as the voice of his/her constituency, she/he could easily be accused of being unrepresentative on other grounds (Bangura 1996:43). This is because most representatives are not at all representative in reflecting the social makeup of their districts, such as class, career, gender, age, education, and ethnicity. For the most part, all of the representatives of African-American majority congressional districts are of middle- or upper-class professionals, who are lawyers and/or former state politicians, much better educated than their constituents, older--with the exception of Cleo Fields, and of African decent. The gender is majority female of the districts that were affected. However, the majority of African-American representatives in Congress are male. A limitation of this theory, therefore, is that there is no method to determine if the representative reflects the social makeup (ethnicity) of the district. For instance, all of the African-American congressional districts were determined to be majority African-American, because of the percentage of African-Americans living in those districts. Finally, it may be true that most representatives are not at all representative in reflecting the social makeup of their districts, but to have a United States legislature that is mostly comprised of white males is not equitable. The reason for this is that a government that corresponds to the characteristics of the general public is a government that could be effective in addressing the concerns and needs of its diverse population.

As stated earlier, the formal position taken in this study is that the recent redistricting of minority-majority congressional districts in the South will have an adverse effect on minority representation in Congress. So, the major propositions suggested can now be assessed.

The first proposition, P1, if all minority-majority congressional districts are considered unconstitutional, then this will have an adverse effect on minority representation in Congress, could not be definitively determined. When the minority-majority African-American congressional districts were considered unconstitutional, they could not be redistricted. The reason for this is that the election process had already taken place in those districts, and redistricting those districts would have violated the legality of the electoral process. As for the second proposition, P2, if the redistricting of minority-majority congressional districts increases, then the democratic stronghold of minority partisanship will dilute, it is apparent that the majority of African-American congressmen and women are democrats. So, if this process of redistricting minority-majority African American congressional districts continues, then the democratic stronghold of minority partisanship will dilute in Congress.

CONCLUSION

As once stated,

> Some time in the past it was necessary to have black faces in Congress to serve as role models for other young people who would aspire to be elected officials, to be at the table so that our voices would be heard, to insure that we were not overlooked. But at some point, we have to question the creation of districts in which the election of a black person is an end with itself. I believe that it is not an end in itself, it's a means to an end, and the end to be accomplished is to win. It takes a majority of the votes, 218, to win in Congress (Swain 1993:212).

Indeed, the purpose of creating minority-majority African-American congressional districts is to win: that is, to obtain the necessary votes to pass appropriate legislation that addresses the concerns and needs of African-Americans and other minorities. Every ethnicity needs to be at the table so that their voices could be heard, and to insure that they are not overlooked. This is why minority-majority African-American congressional districts should not be redistricted.

A Quantitative Study of the Longevity of Vietnam-Era Disabled Veterans

Joseph L. Singleton, Jr.
Department of History and Government
Bowie State University
Bowie, Maryland 20715

Faculty Advisor:
Dr. Abdul Karim Bangura

This essay tests for a relationship between the predicted influence of the effect of longevity to those veterans who are disabled, and from the Vietnam-era. It is hypothesized that the more veterans benefits a disabled Vietnam-era veteran receives, the longer the lifespan will be for that veteran. The more effective research method for this type of study was time series. This allowed for the analysis of the change that took place in the relationship between the independent and dependent variables over time. The final analysis showed that veterans benefits to disabled Vietnam-era veterans did have some positive and statistically significant relationship with longevity.

INTRODUCTION

Studies on the Vietnam era and veterans are concentrated on these veterans' readjustment counseling programs (see, for example, Washington 1985, Browne 1973). Given the nature of their studies, the authors do not seek to examine the plausible relationships between veterans benefits to disabled Vietnam-era veterans and longevity. Instead, these authors concentrate exclusively on the issue of readjustment counseling programs. Thus, this essay attempts to test for whether there is a relationship between the predicted influence of veterans benefits and the longevity of those disabled veterans from the Vietnam era. It is suggested that the more veterans benefits a disabled Vietnam-era veteran receives, the longer the lifespan will be for that veteran. Thus, the major question of this research is as follows: Can a disabled Vietnam-era Veteran without veterans benefits have a long life, lacking the assistance of those benefits? This is important because the benefits veterans receive, regardless of their status, are very important for their sustenance. This study covers the period from 1990 to 1995 because it is the timeframe for which pertinent data on the topic are available.

RESEARCH METHODOLOGY

The research methodology employed for this study is quantitative. The theoretical framework used is presented below. In that framework, the independent variable is veteran benefits to disabled Vietnam-era veterans. The dependent variable is longevity. The basic assumption from the theoretical framework is as follows: There is a relationship between veteran benefits of disabled Vietnam-era veterans and their longevity.

Veterans Benefits to
Disabled Vietnam-Era Veterans → Longevity
(Independent Variable) (Dependent Variable)

Consequently, the hypothesis for this research is H1: The more veterans benefits a disabled Vietnam-era veteran receives, the longer the lifespan will be for that veteran. This study is therefore a micro level analysis, meaning that data for the measurements were taken from a microcosm of the total veteran population. The data were derived from reports prepared by the Department of Veterans Affairs, c/o Laboratory Services; Paralyzed Veterans of America, c/o Baltimore Service Office; and The National Center for Veteran Analysis and Statistics Service, c/o Robert E. Klein, Ph.D., and Janet M. Somers. Therefore, the type of data collection technique used was document analysis because the data already existed. These documents are running records covering a long period of time.

The research design employed in this study is a simple time series design because it suggests how veteran benefits to disabled Vietnam-era veterans affect their longevity from 1990 to 1995. This design can be diagrammatically represented as follows:

$$X \quad O_{1990} \ldots O_{1995} \qquad [1]$$

In the preceding design, X represents the effect of veterans benefits to disabled Vietnam-era veterans and O represents observations of the outcome, longevity, over time.

DATA ANALYSIS

The data for this research were analyzed in two stages: univariate and bivariate. The statistical package used to compute the data was GB-STAT. The statistics used at the univariate stage are the mean and standard deviation. The results of the data generated from the computer run for these statistics are summarized in Table 1.

The results in Table 1 show that from 1990 to 1995, the mean veterans benefits to disabled Vietnam-era veterans (VBDV) is $2.9 million and the standard deviation is $3.7 million, and not statistically significant at the .05 level. The mean for longevity (LONG) is 50.16 years and the standard deviation is 1.47 years and, thus, statistically significant at the .05 level. The procedures used for analyzing the data at the bivariate stage are correlation (which measures the strength of the relationship between the independent and dependent variables), and regression (which shows the nature of the relationship between them). Tables 2 and Table 3 are tabular representations of the results after the computer runs for the bivariate analysis.

TABLE 1: Mean and Standard Deviation

VAR	MEAN	SAMPLE STD. DEV.	SAMPLE VARIANCE	COEF OF VAR.
VBDV	2.968742E+08	3.725916E+07	1.388245E+15	.1255
LONG	50.16667	1.47196	2.16667	.02934

TABLE 2: Correlation Matrix

	LONG
VBDV	.97605**

* * PROBABILITY < .01 * PROBABILITY < .05

As Table 2 reveals, the correlation coefficient of .97605 shows that statistically, there is a positive and significant correlation between veterans benefits to disabled Vietnam-era veterans and longevity at the .01 level. The results generated after the computer runs for the regression equation are summarized in Table 3.

TABLE 3: Explanation for the Variation in Longevity

Linear Y = A + B * X
Linear Y = 38.7191 + 3.856037E-08 * X

UnAdjusted R^2 = .9527
Correlation Coefficient = .9761
Anova for Prediction F = 80.5276
Chance Probability P = .ooo9
STD> Error of Estimate = .3578
Variance of Estimate = .128
Degree of Freedom = 1 and 4
With = VBDV and Y = LONG

As Table 3 shows, a regression coefficient of .9761 means that there is a statistically significant relationship between longevity and veteran benefits to disabled Vietnam-era veterans at the .01 level. Therefore, the hypothesis examined in this study, H1: The more veterans benefits a disabled Vietnam-era veteran receives, the longer the lifespan will be for that veteran, is accepted.

CONCLUSION

This study was originally based on the premise that longevity is dependent upon the veterans benefits a disabled Vietnam-era veteran receives. As such, the study of the relationship among these variables addresses real-world actions. The most effective research method for this type of study is that of a time series. This allows for the analysis of the change that took place in the relationship between the independent and dependent variables over time. The final analysis showed that veterans benefits to disabled Vietnam-era veterans did have some positive and statistically significant relationship with longevity. For future research, different independent variables could be used to explore other plausible explanations for the longevity of these veterans.

The 1996 Albanian Elections:
Corruption? Or a Catalyst for Democracy?

Christopher Thomas Johnson

Department of Political Science
Hamline University
1536 Hewitt Avenue
St. Paul, MN 55104

Faculty Advisor: Dr. Karen Vogel

Since the fall of Communism in 1990, Eastern Europe has been in transition to democracy. The transition has been rather rocky in many countries, with irregularities in their electoral processes. This essay is a case study of electoral problems in Albania. The 1996 Albanian elections, which were marked by irregularities, helped cause the crisis of 1997.

INTRODUCTION

For the third time since the end of communism in 1990, the citizens of Albania elected a President on May 26, 1996. The election was marked by irregularities perpetrated by the ruling Democratic Party and its leader: President Sali Berisha. In this essay, the electoral process and the results of the 1996 Albanian elections will be discussed. The current crisis in Albania will also be analyzed.

THE POLITICAL PARTIES

In order to be able to understand the context of the elections, one needs to look at the political parties in Albania. Albania has a multi-party system. But in the 1996 election cycle, the two main parties dominated. Minor parties formed coalitions with the main parties. For each of the two main political parties, who leads them and who their are aligned with and supported by will be described, beginning with the incumbent Democratic Party.

The Democratic Party, which claims to be oriented toward democracy and right-wing on the ideological spectrum, is led by Sali Berisha, who was first elected president of Albania in the country's second post-communist elections in 1992 ("Who's Who in the Election," 5-27-96). President Berisha, a former communist and a heart surgeon, helped to lead the 1990 revolution which toppled communism ("Who's Who in the Election," 5-27-96). The main issue Democrats ran on was how they defeated Communism in 1990 (Gerencser, Steven, 9-27-96).

During the 1996 Democratic Party convention, President Berisha made a "Union for Democracy," a coalition with other right-wing and centrist parties in Albania ("Democrats Call to Prevent Return of Former Communists," 4-8-96). This coalition was made in an attempt to gain a big enough majority to prevent the Socialists from gaining power ("Democrats Call to Prevent Return of Former Communists," 4-8-96).

Berisha also brought in leaders from different Western European countries to campaign with him. Michel Pericard, who is the Parliamentary head of France's ruling Rally for the Republic Party publicly campaigned with Berisha as did Klaus Buehler, representative in the Council of Europe for German Chancellor Helmut Kohl's conservative party ("Rights Group Protests Foreign Interference," 5-6-96). Italian President Oscar Luigi Scalfaro and former German President Richard von Weiszaecker also made campaign appearances with Berisha ("Rights Group Protests Foreign Interference," 5-6-96).

Berisha had help from the Roman Catholic Church in Albania, which issued a statement, signed by clergy, that indirectly supported Berisha ("Roman Catholic Leaders Urge Albanians to Vote," 5-20-96). The statement read in part, "We...pray to God that through the benefit of voting...real Democracy can win once and for all for the honour and glory of God and the benefit of the whole nation" ("Roman Catholic Leaders Urge Albanians to Vote," 5-20-96).

The Socialists, or the former communists, were led by Fatos Nano who was an economist in the former Institute for Marxist-Leninist Studies during the regime of communist leader Enver Hoxha ("Who's Who in the Election," 5-27-96). He was arrested in 1993 and jailed in 1994 for embezzlement in an Italian aid scandal ("Who's Who in the Election," 5-27-

96). Many human rights groups criticized his imprisonment as being unjust ("Who's Who in the Election," 5-27-96). He escaped from prison during the 1997 crisis (Puto, Arben, 4-22-97).

In an effort to gain a majority and win the election, the Socialists made an alliance like the Democrats ("Socialists to Join Forces With Other Leftists," 4-29-96). At their party's convention, the Socialists announced a coalition with five other left-wing and centrist parties that would give them an electoral victory, or at the very least, a working majority in the parliament ("Socialists to Join Forces With Other Leftists," 4-29-96).

Because of the economic conditions in Albania, tensions in the electorate were high, and the ruling coalition under Berisha was fearful of losing support. It is not surprising that irregularities began to emerge during the campaign process.

IRREGULARITIES

One type of irregularities in the Albanian electoral process was when laws were misused to unfairly benefit or harm one party over another. An example of this was Albanian Law that prevented former communists and their secret police from running for office until 2002 ("Albanian Elections Set For May 26," 4-15-96). This prevented the Socialists from running many of their candidates even though Sali Berisha himself was a communist ("Albanian Elections Set For May 26," 4-15-96).

Another way the Democrats misused law to unfairly benefit themselves and harm their opponents was how they controlled Albanian television (Gerencser, Steven, 9-29-96). The government controls television news (Gerencser, Steven, 9-29-96). So the news coverage was tilted in favor of the Democrats and against the Socialists (Gerencser, Steven, 9-29-96).

The Democrats also broke election law. An example of this is although there is a law which prohibits non-Albanian citizens from running an election campaign, Berisha brought in several Western European diplomats who helped campaign for he and the Democrats ("Rights Group Protests Foreign Interference," 5-6-96).

Many instances of police harassment occurred against opposition candidates and newspapers. In Albania there is no independent press, with newspapers tilted in favor of a party (Gerencser, Steven, 9-29-96). So the police would go into an opposition newspaper office, detaining the editors for questioning (Gerencser, Steven, 9-29-96). They would claim to be investigating a supposed libelous news report out of that newspaper (Gerencser, Steven, 9-29-96). This would effectively shut them down for the day so that they would be unable to print that day's newspaper (Gerencser, Steven, 9-29-96). It can also be argued that such investigations by the police were a form of indirect censorship, because it made newspapers less likely to publish certain articles against the government in fear of being harassed (Gerencser, Steven, 9-29-96).

Another way the police harassed opposition candidates was by breaking into their offices ("Police Disrupts Opposition Campaign, Daily Says," 5-6-96). In one report, the police stormed into a Socialist Party office, ripped down the pictures, flags, banners, tearing the place apart ("Police Disrupts Opposition Campaign, Daily Says," 5-6-96). Police also detained the workers, questioning them as to whether they were running a libelous campaign ("Police Disrupts Opposition Campaign, Daily Says," 5-6-96).

The police weren't the only ones guilty of harassing the opposition. Four days before the election in Durres, Albania, Democratic supporters disrupted a legal Socialist rally by assaulting vehicles carrying Socialist Party members and cutting off power to the rally, canceling it ("Police Arrests Suspected Rally Killers," 5-27-96).

One of the most blatant examples of harassment of the opposition occurred in Shkroder, Albania, which is a rural area in the north. Dr. Steven Gerencser, an election observer, and other American observers traveled to the city to view a Socialist rally which was planned there (Gerencser, Steven, 9-29-96). They were on the only road leading in to Shkroder when they hit a traffic jam and stopped (Gerencser, Steven, 9-29-96). Because the area was so rural, a traffic jam seemed strange, and the observers got out of their car to investigate what was happening (Gerencser, Steven, 9-29-96). The observers continued up the road and saw a semi-truck parked sideways on the road, blocking both lanes of traffic (Gerencser, Steven, 9-29-96). The truck had a Democratic Party banner on it, and Democratic Party supporters held a rally on the road (Gerencser, Steven, 9-29-96). The Americans talked with the police at he sight, who offered to clear a path for them to go through (Gerencser, Steven, 9-29-96). Dr. Gerencser said that although they were offered to be allowed to go through, it was clear that the police were not willing to break up the Democratic rally (Gerencser, Steven, 9-29-96). The

American observers turned around, going to the nearest city to talk with the Socialists (Gerencser, Steven, 9-29-96). The Socialists were prevented from being able to take the road into Shkroder, and had to cancel their rally (Gerencser, Steven, 9-29-96).

Just as Socialist candidates were harassed, Albanian voters were harassed too. Dr Gerencser saw that during voter registration, citizens who were believed to be pro-Socialist had a difficult time registering (Gerencser, Steven, 9-29-96). They either had the validity of their forms of identification questioned, or had to provide more than one form of ID to vote (Gerencser, Steven, 9-29-96). On the other hand, voters who were thought to be pro-Democrat were able to register very easily (Gerencser, Steven, 9-29-96). Some were able to register family members who weren't even with them (Gerencser, Steven, 9-29-96). Voters were also intimidated when they entered the polls, because armed policemen and secret police were present ("Two Monitoring Groups Call Albania Vote Marred," 5-30-96).

In addition to voter intimidation, actual vote fraud took place. Several locations reported unsecured ballot boxes (ballot boxes that were unlocked or not guarded) ("Two Monitoring Groups Call Albania Vote Marred," 5-30-96). There were also reports of altered votes and ballot boxes which were stuffed with illegal ballots ("Two Monitoring Groups Call Albania Vote Marred," 5-30-96).

These irregularities heightened the mistrust of the government by the people, and would set the stage for things to come.

ELECTION DAY AND ITS AFTERMATH

In the days and weeks before the election, many people believed that the race between the Democrats and the Socialists would be very close, within about five points (Gerencser, Steven, 9-29-96). But by the middle of election day, the Socialists pulled out of the election, citing the many irregularities which took place (Gerencser, Steven, 9-29-96). The Democrats won with more than 67% of the vote, while the Socialists had less than 25% of the vote ("Riot Police Beat and Arrest Albanian Election Protesters," 5-29-96).

Although President Berisha was declared the winner in the Albanian elections, he still banned an opposition rally to be held the day after the elections ("Riot Police Beat and Arrest Albanian Election Protesters," 5-29-96). In what many experienced election observers said was the most violent aftermath of any election in Eastern Europe since the fall of communism in 1990, many Socialists demonstrated against the government and were beaten and jailed by the police. ("Riot Police Beat and Arrest Albanian Election Protesters," 5-29-96).

REACTIONS TO THE ELECTION

Forty out of 53 O.S.C.E. observers said they witnessed irregularities and basic electoral corruption at the polls ("Riot Police Beat and Arrest Albanian Election Protesters," 5-29-96). More than a dozen of the observers signed a statement saying the election did not meet "international standards for free and fair elections" ("Riot Police Beat and Arrest Albanian Election Protesters," 5-29-96). They also reported that in many cases "the number of ballots cast exceeded the number of signatures on voter lists" ("Eleven OSCE Observers Criticize Elections," 6-3-96). And they called for a second round of elections to be held in districts where the most blatant examples of irregularities were found ("Eleven OSCE Observers Criticize Elections," 6-3-96). In The O.S.C.E.'s final report on the May 26 Albanian elections, its members found that 32 Albanian election laws out of 79 were broken ("Eleven OSCE Observers Criticize Elections," 6-3-96).

Human Rights Watch, a New York based organization, also criticized the election, calling on the United States and European governments to declare the Albanian elections invalid ("Albania's Reformer Turns Autocrat," 6-1-96). The European Union called on Berisha to hold a new election in some districts, with France and the U.S. agreeing ("Albania's Reformer Turns Autocrat," 6-1-96).

Because of the criticism of the May 26 elections, polling was re-run in 17 districts ("Foreign Observers Say Albania Poll Rerun Was Fair," 6-24-96). This second polling was considered free and fair by international observers ("Foreign Observers Say Albania Poll Rerun Was Fair," 6-24-96). It was interesting, because the Democrats won in all 17 districts with huge majorities ("Foreign Observers Say Albania Poll Rerun Was Fair," 6-24-96).

CONCLUSION

The current crisis in Albania began in January 1997. After losing about $1.5 billion in

BEST COPY AVAILABLE

"pyramid schemes," the citizens of Albania began violent protests against the government ("Rebel Albanian Port Prepares to Repel Attack," 3-9-97). Pyramid schemes are fraudulent investments where early investors are paid high interest from the contributions of later investors, with operators of the schemes taking a high percentage of the investments for themselves ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). When no new investors can be found, the scheme goes bankrupt ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). Albanian citizens earn only $60-$80 a week, which makes the pyramid schemes so attractive ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). To invest in the pyramid schemes, many Albanians sold their homes, livestock and other assets ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). Almost every family in Albania had some money in a pyramid scheme (Puto, Arben, 4-22-97). These schemes were allowed to take place, because there were no regulations against them.

Because so many people lost so much money, and because Albanians are so poor, violent protests occurred ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). Albanians protested because they blamed President Berisha for allowing the schemes to take place ("Violent Protests of Pyramid Schemes Spread in Albania," 1-27-97). In fact, leaders of opposition parties say, that money from some of the pyramid schemes went to finance the Democratic Party's 1996 campaign ("Albanians Clash in Pyramid-Scheme Protest," 1-20-97). While Berisha denies this, there is evidence that the government knowingly allowed the schemes to take place and was friendly towards their operators. In fact, some of the biggest funds endorsed Berisha and held functions for members of the Democratic Party ("Albania Calls An Emergency As Chaos Rises," 3-3-97). Some Democrats even had insignias from the funds on their campaign posters ("Albania Calls An Emergency As Chaos Rises," 3-3-97). Even though officials from the World Bank, the International Monetary Fund, and the United States warned Berisha of problems with the pyramid schemes, they were not stopped until after most of them went bankrupt ("Albania Calls An Emergency As Chaos Rises," 3-3-97). All of this, along with previous electoral irregularities, has caused a loss of confidence in the government by the people.

During this crisis, Berisha is refusing to step down as President. A new coalition government was formed, with Berisha as President and members of the Socialist Party and the Democratic Party in his cabinet (Puto, Arben, 4-22-97). Berisha also had himself appointed to another five year term ("Albania Chief Tightens Grip In Crackdown on Protests," 3-4-97). These actions seem to suggest the demise of democratic government in Albania. However, Berisha has agreed to new elections to be held in June 1997 (Puto, Arben, 4-22-97).

Whether or not these elections will take place is uncertain. It is hoped that demonstrations will stop as the elections approach. The UN has sent troops to Albania for three months to oversee the distribution of aid (Puto, Arben, 4-22-97). With troops in Albania during the month the elections take place, there is a chance that they might be able to create stability. But what really needs to happen is to have the coalition government sit down and formalize a new constitution. Currently, there is only an interim constitution in Albania. This means that a free and independent press is not guaranteed, nor is the right to assemble and form oneself into interest groups. Until these fundamental rights are guaranteed, there is little chance of legitimate support from the people or-Albania becoming truly democratic. If President Berisha wants to be credible in his country and around the world, he must allow these fundamental reforms to take place.

The Role of the International Law of the Non-Navigational Uses of International Watercourses in Resolving the Disputes Over Access to Freshwater in the Middle East

Jason Woolwine

Faculty Advisor:
Gary Prevost Ph.D.

Relationships among countries of the Middle East were, and continue to be significantly affected by and played out in the use of water and the policies that surround their use. While many methods exist by which to deal with the water issue, the most universal one is that of international law. Although international law exists to deal with problems such as this, its effectiveness is questionable. This will be discussed in conjunction with two case studies: the groundwater in the West Bank, and the Euphrates River.

There are several reasons why people have failed to consider water as a major force in the Middle East. The main reason is that when someone looks at the Earth, one sees it is covered mostly by water and are left with the impression that there is plenty of water to go around. What one fails to realize is that the only drinkable water is freshwater, and that only accounts for approximately 2 percent of the world's water supply. Of this 2 percent, 87 percent is embedded in ice caps and glaciers, buried deep underground, or contained in the atmosphere. In fact, of all the freshwater in the world, only about one-third of 1 percent is available for human consumption and survival (Starr 1993). Now add to that equation the fact that the minuscule amount left is spread out unevenly all over the world, and not according to need. Only after realizing all of this can one begin to grasp exactly how scarce water, the element essential for all life, really is.

Just how governments will deal with water is the concern. While States may chose to continue their current policies without concern for water issues, time will catch up with them. To allow the status quo to continue will make the problems more explosive and pressing in the future. The Middle East is a volatile enough area without adding to the problems.

There are then two possibilities for action, either unilaterally, or multilaterally. Acting unilaterally is of course better than no action at all. Yet it too is problematic. There are times and issues when a State acting on its own can resolve a problem, or diffuse a situation by a change in domestic policy or even by acting alone on the international level. However, the issue of water rights and international rivers, by their very nature can not be resolved by a single actor working alone. In addition, by acting on its own a State, in almost all cases, will fail to take into consideration the needs of its neighbors. It will focus solely on its own concerns, plans, and potential for exploiting a given resource, in this case water. The resolution of disputes over rights to international rivers will require a collective effort. It is international law that can function as a mediator between disputing states. However, international law is a course of action that lacks a universal enforcement mechanism. This calls the ability of international law to function successfully into question. It is exactly because of its questionable status that one must ask the question: is the international law on the non-navigational uses of water capable of providing realistic solutions to the disputes over freshwater in the Middle East?

WEST BANK CASE STUDY

Israel's water is transported through a system of pipes and aquifers called the National Water Carrier. The National Water Carrier is made up primarily of three aquifers. Two of these, the "Mountain" and "Western" are located in what Israel calls Judea and Samaria, and what the Arabs call the West Bank. Only one aquifer, the "Coastal" aquifer is located in the original 1948 borders. This system is vital to the delivery of water within the country and the security of the carrier is viewed by many, especially the government, as an essential part of national security. The location of these aquifers is very important and it sheds some light on why Israel is so reluctant to give up the West Bank.

The West Bank has an annual water supply that varies depending on the rainfall in the region. Exactly how much water is in the West Bank Israel refuses to comment on and the Palestinians to this point have been unable to come up with any figures of their own. However, it is known that Israel takes 85 percent of the water from the western aquifer, and gets between 30-40 percent of its total water supply from the West Bank, (Stutz 1994). If the West Bank water is so important to Israel, is peace a possibility? It has become clear that water is an essential variable in any peace equation, but can all parties agree on a division of the water?

APLLICATION OF DRAFT ARTICLES TO WEST BANK GROUNDWATER

The application of international law to the groundwater in the West Bank is an interesting situation. The problem is the fact that the West Bank is an occupied territory and as such would more likely fall under the laws concerning belligerent occupation than the draft articles. Additionally, The Palestinians are not considered a state in the strict legal sense, and as a result would not be considered party to the draft articles. With this case study however the intention is not to determine what current allocations should be, but to determine if allocations should change from their current level given the existence of a Palestinian state in the West Bank. For that to take place, the draft articles must be applied to the situation at hand.

The application of international water law was helped when the Israeli government for the first time officially recognized Palestinian rights to West Bank water in accords signed in September of 1995 (Reuters 1996). Additionally, both sides have agreed that the water issue should be resolved through the principle of equitable utilization (Elmusa 1996). Equitable utilization is the basis of the International Law Commission's draft articles. While all 33 of the articles are important in their own right the focus will only be on articles 5, 6, 7, and 21.

The first article of importance is Article 5. This article establishes that states should utilize an international watercourse in an equitable fashion. Article 5 sets out the fundamental rights and duties of States with regard to the utilization of international watercourses for purposes other than navigation (ILC 1994). Thus a watercourse State has both the right to utilize an international watercourse in an equitable and reasonable manner and the obligation not to exceed its right to equitable utilization or, in somewhat different terms, not to deprive other watercourse States of their right to equitable utilization (ILC 1994). This does not establish a rule that states should have an equal amount of water, instead, it establishes equality of rights to utilize the water. But what is equitable utilization? Jonathan Wenig argues that, "to the extent that existing allocations satisfy existing demands, they are judged as equitable, (Wenig 1995)." It is very apparent that the current apportionment of the West Bank water does not satisfy existing demand. To an extent however this is hard to measure due to the military occupation and governance of the territory. This artificially restricts the Palestinian demand for water due to external restrictions places on agriculture and industry. Although optimal utilization has an inherent bias towards existing uses of water, when inequalities still exist, the focus shifts towards redistribution (Wenig 1995). Not only do inequalities exist, there is also appreciable harm cased by these regulations on the Palestinian people. A use that causes appreciable harm is inherently inequitable (Wenig 1995). As a result of these impediments to the Palestinians (as discussed above) a the West Bank water needs to be re-allocated.

While it is easy to say that the waters should be re-allocated, that hard part is in determining how equitable utilization should be determined. It is at this point that Article 6 enters the picture. Article 6 lists factors relevant to equitable and reasonable utilization. This section includes such factors such as the social and economic needs of the watercourse states, the population dependent on the watercourse, and geographic or hydrographic factors among others. Sharif Elmusa argues that the relevant factors "boils down to the socially and economically based water needs and the relative ability of the two sides to tap alternative water sources, (Elmusa 1996)." These two factors justify a re-allocation in favor of the Palestinians. The aquifers of the West Bank are the sole water source for the Palestinians. Although they border the Jordan River, they are prevented from utilizing it as a result of the military occupation. The Palestinians also have neither the capital or technology to tap alternative sources of water. The Israelis however are world leaders in water efficient technology and have both the capital and technology for desalination plants. Israel is capable of harnessing nonconventional resources that could provide it with substantial amounts of water. In fact, it announced in 1995 a long-term water desalination program that will produce about one-and-a-half times the amount of water of the entire mountain aquifer by the year 2040 (Elmusa 1996).

Article 7 brings up another factor to be considered in redistributing the waters, that of the obligation to not cause significant harm. While this can easily be applied to the case in favor of the Palestinians, it can also be utilized on behalf of Israel. As noted above, Israel is currently very dependent on the West Bank water. It is very easy to argue that a re-allocation would cause them significant harm. However, in the context of the articles as a whole, Article 7 favors a redistribution favorable to the Palestinians. It does however place limits on that redistribution and obligates those who will in the end determine specific amounts to still consider the Israelis when the aquifers are divided.

The final important article is Article 21. This article is designed to prevent, reduce, and control pollution. Pollution is defined as, "any detrimental alteration in the composition or quality of the waters of an international watercourse which results directly or indirectly from human conduct, (ILC 1994)." A reduction in quality or the increase in saline levels in the aquifer would constitute pollution under the draft articles. Only in considering pollutive actions does the principle of "no appreciable harm" supersede that of equitable utilization (Wenig 1995). This is important because if the overuse of an aquifer results in increasing the salinity of the aquifer, then such a use cannot be allowed to continue, even if it constitutes equitable utilization. In other words, the Palestinians must be careful once they acquire autonomy to not overpump the West Bank water (a major Israeli fear) and increase the salt water intrusion into the aquifers. If they were to do so, the Israelis would have the right to prevent such actions.

Looking over the draft articles it is quite easy to see that they endorse a redistribution of the West Bank groundwater in favor of the Palestinians. Such a division can only be seen as finally establishing equitable utilization and reversing the harms and restriction placed on them by thirty years of Israeli occupation. The draft article however should not be seen as a blank check to the Palestinians to engage in whatever water policies they deem fit. The draft articles do place some restrictions on them. These are found in Articles 7 and 21, the obligation not to cause significant harm and to prevent pollution, in this case from salt water intrusion due to overpumping the aquifers.

EUPHRATES CASE STUDY

The primary conflict over the use of the Euphrates River is the Turkish GAP project and its implications for downstream states. The GAP stands for "Guneydogu Anadolu Projesi" or translated from Turkish, the Southeast Anatolia Project. It is a giant $32 Billion project of 21 dams, 19 hydropower plants, and irrigation canals for the southeastern region of Turkey (Washington Times 1996). The rural southeast region of Turkey is populated mostly by Kurds, who have always harbored separatist dreams. A central political premise on which the GAP initiative is predicated is that as long as the rural Kurdish areas remain poor, the locals will be susceptible to Marxist and nationalistic ideas. Conversely, a thriving economy with many job opportunities would strongly inhibit the inhabitants from toying with such destabilizing ideas (Faure 1993). In essence, GAP seeks to buy off the Kurdish population and at the same time significantly decrease the appeal, effect, and importance of Kurdish independence movements such as the PKK.

At the same time though, GAP is a project that can provide immense benefits to Turkey through the increased electrical output, increased irrigation and agricultural output there by producing export income, as well as incredible economic growth. GAP will also serve as a means of flood control for downstream riparians at no cost to them and water storage is most effective done near the headwaters for flood control and to lessen evaporation

(Green 1993). The principle part of GAP is the Ataturk Dam, which has the capacity of nearly 49 billion cubic meters (greater than that of the entire yearly output of the Euphrates) and, when finished, will be the fourth largest construction in the world. The canals draining out from the reservoir will be able to irrigate 143,000 hectares of land, making the region a sort of Eden, capable of producing three harvests a year (Allan 1995). GAP should not be viewed solely as a means of placating the Kurds, but also as a project with tremendous national importance for the country as a whole.

Syria and Iraq are very concerned about the GAP project. Once completed, it would have a drastic impact on the flow of the Euphrates they receive. A fully functioning GAP could cut Syria's permanent share of the Euphrates by up to 40 percent and Iraq's by 80 percent (Cohen 1991).

APPLICATION OF DRAFT ARTICLES TO EUPHRATES RIVER

Article 5 establishing the need for equitable utilization is the fundamental basis of the draft articles. Within the commentary to Article 5 is found the statement that "there is no doubt that a watercourse State is entitled to make use of the waters of an international watercourse within its territory. This right is an attribute of sovereignty and is enjoyed by every State whose territory is traversed or bordered by an international watercourse, (ILC 1994)." This provides the basis of the Turkish claim to be able to do with the Euphrates while it is within its borders as it sees fit. Wenig's point that, "to the extent that existing allocations satisfy existing demands, they are judged as equitable, (Wenig 1995)" is once again very important to the discussion. As long as Syria and Iraq's needs are met, Turkey does not violate international law with the continuation of the GAP. It is questionable however if Syria has enough. Although the majority of their hydropower and dam problems can be attributed to poor planning (dams that were designed for Siberia, not Syria), and Turkey cannot be expected to compensate Syria for poor planning by increasing the flow of the Euphrates into Syria, Syria could be justified in asking for an increase to satisfy irrigation needs and increases in population.

In Article 6 are found the factors to use in order to determine equitable utilization. Looking at the relevant factors such as climate, geography, and hydrology, it is very possible to assert that Turkey is entitled to a large portion of the Euphrates. Turkey not only contributes almost all the water to the Euphrates but also has a large share in the area of its drainage basin and portion in the river channel (Kliot 1994). This is consistent with the current situation. As long as the other riparian needs have been met, the remainder, and what should be a majority, of the Euphrates water can be utilized by Turkey.

Article 7 obligates States to not cause other riparians significant harm. A use that causes harm is inherently inequitable (Wenig 1995). While the current use does not engage in significant harm to any of the riparians, this is a clause to bear in mind for the future. As noted previously, a completed and fully operational GAP will have a drastic affect on Syria and Iraq. This would, by any stretch of the imagination, constitute the significant harm that the draft articles seek to prevent. The impact of this is that that GAP project will have to be re-evaluated, or at least some agreed upon method of compensation for the lower riparians will have to be developed. The likelihood of that if very slim considering the importance of the Euphrates to both Syria and Iraq. Equally unlikely is the prospect that Syria and Iraq will give their permission for the construction of a completed GAP.

All of this of course assumes that Turkey will be willing to implement the draft articles. A consideration that can only be considered a guess at this point. If Turkey remains adamant in their claims that the Tigris and Euphrates Rivers are not international watercourses, as they have been in the recent past, then they will not consider themselves bound by the draft articles. To accept the draft articles would mean turning their back on GAP, a prospect they are completely unwilling to do. Turkey is in a relative position of strength. As the upper riparian, its water supply is not controlled by either Syria or Iraq. As a result of this, it is Turkey that will decide if the draft articles are to be successfully applied to the Euphrates River. Most importantly though, it is protected from repercussion by the state of international law. No effective mechanism exists to force states to comply with international law. The dispute resolution mechanism of the draft articles itself fail to provide

BEST COPY AVAILABLE

a solution either. Article 33 on dispute resolution assumes that all parties want to reach a solution. The Article assumes a situation that rarely exists in the real world.

CONCLUSION

International law is capable of providing a means by which an equitable solution can be reached. As the case studies point out, international law can work successfully if its application is agreed on by all parties. Without that agreement, situations such as the Euphrates case study will be the norm. This can be explained by the lack of an effective enforcement mechanism. While the direct application of international law could be labeled as suspect, it does provide indirect benefits. The discussion and formulation of international law serves to shape state practice. It is questionable that the Israelis and the Palestinians would agree to equitable utilization of their waters (the primary principle of the ILC draft articles) without the continuing formulation of those principles by the international law community.

Trends in the Eisenhower Administration:
A study of Inflation, Unemployment, and Presidential Popularity

Dr. James Lindeen
Department of Political Science and Public Administration

A strong approval rating for a President allows that President to exercise a large amount of political power, both within his party and outside of it. What most affects Presidential popularity? How can a President ensure that his popularity will not decline beyond a point of no repair?

Recent elections (since the 1980's) have shown that an incumbent (either President or party) with a strong economy will win (Reagan in 1984, the Republican Party in 1988, Clinton in 1996). On the same note, an incumbent struggling with the economy (Bush in 1992, the Democratic Party in the 1994 Congressional elections) will suffer in an election. The results of recent elections strongly suggest that the economy is one of the foremost factors in determining a President's popularity and influence.

This project examines the relationship between Presidential Popularity and economic indicators, specifically inflation and unemployment.

Eisenhower is an ideal President to study in dealing with inflation, unemployment, and popularity. Eisenhower's term of office was calm: he was not forced to deal with any major international crises and the economy was relatively stable. Eisenhower was the first President to effectively use Keynes' notion of counter-cyclical planning in managing the economy. As a result, under the Eisenhower Administration, the nation experienced three business cycles, each of a relatively "normal" nature. Table 1 shows the U.S. Business Cycles from the close of 1854 to March 1991.

Eisenhower entered office in the midst of a forty-five month period of expansion, and the economy peaked in July 1953. This peak was followed by a ten month period of contraction, and Eisenhower's first trough occurred in May 1954. The economy rose again, peaking in August 1957 (after 39 months of expansion), and, over the next eight months, fell to a second trough under Eisenhower in April 1958. The final peak in the economy during the Eisenhower Administration occurred two years (24 months) later, in April 1960 (Lindeen, *Governing the Economy*, 1994).

The measures by which one can measure the state of the economy are numerous, so it was necessary to study two or three indicators against which Presidential Popularity could be compared. Inflation and unemployment were selected. The choice was not random: according to Kiwiet in *Macroeconomics and Micropolitics*, inflation (the substantial rise of prices caused by an undue expansion in paper money or bank credit) and unemployment are the most watched economic indicators. Kiwiet further contends that the inflation rate is generally used by Republicans to judge the state of the economy, while Democrats tend to use the unemployment rate to judge the state of the economy.

Note Numbers in bold face indicate periods of expansion or contraction that occurred during wartime
Source National Bureau of Economic Research, Cambridge MA

Table 1: U.S. Business Cycles

The hypothesis on which the research was based stated that fluctuations in unemployment and inflation would lead corresponding changes in Presidential popularity. Increases in the unemployment rate or the inflation rate would precede a drop in Presidential popularity, while drops in the economic indicators would precede a rise in popularity. The lead time for the indicators should be about one month.

The data to be studied was collected from three sources. Statistics on inflation were from the U.S. Department of Commerce, while the monthly unemployment rate was supplied by the U.S. Bureau of Labor Statistics. Presidential popularity figures came from the Gallop Poll Archives. Presidential popularity is a variation of approval rating: the presidential popularity was obtained by eliminating the "no opinion" category and readjusting the approval rating to be out of 100%.

$$\frac{\text{Approval rating}}{100\% - \%\text{ with no opinion}} \times 100\% = \text{Presidential Popularity}$$

Equation 1: Conversion of Approval Rating to Presidential Popularity

For example: in January 1953, the Gallop Poll reported that the President's approval rating was 78%. Twelve percent of those surveyed did not approve of Eisenhower's actions in office, and ten percent did not have an opinion about the Eisenhower Administration. The ten percent without an opinion were eliminated from the study, and Presidential popularity was then determined by reproportioning the approval rating: [78% / (100%-10%)] x 100% = 87% Presidential Popularity.

BEST COPY AVAILABLE

Comparison of the economic indicators and Presidential popularity was done through multiple time series regression analysis. The first analysis, comparing the numbers without any lead or lag time produced a 44.0% correlation with inflation, a 65.0% correlation with unemployment, and a 69.5% correlation with both indicators. Scattergram analysis of the numbers, however, suggested that a relationship between the numbers could be found with lead or lag times. The following diagrams show the analysis used to determine the appropriate lead/lag time for inflation and unemployment:

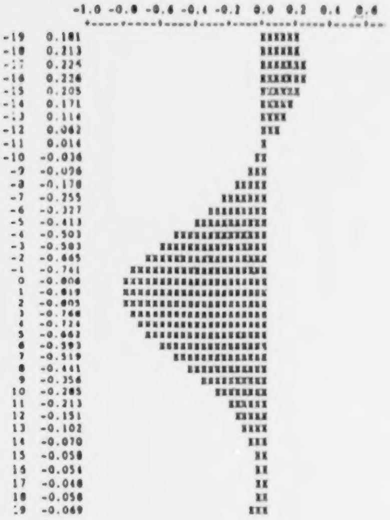

Figure 1: Unemployment
Analysis Data

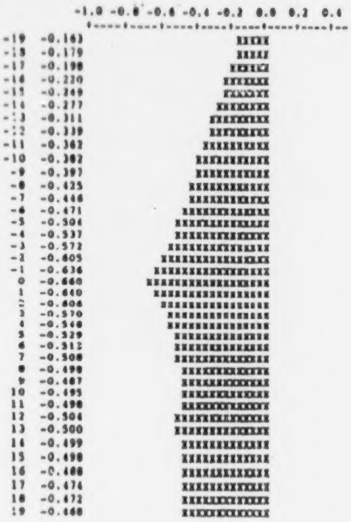

Figure 2: Inflation Rate
Analysis Data

The regression analysis suggested a one month lag for the unemployment rate (the peak is at -0.819, positive one), and no lead or lag for inflation (the peak is at -0.660, zero). With the one month lag in unemployment, the scattergram diagram indicated a tighter relationship between unemployment and Presidential popularity:

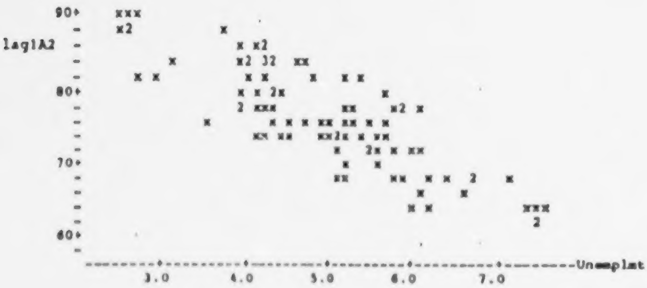

Figure 3: Scattergram Analysis of Unemployment-Presidential Popularity (1 month lag)

BEST COPY AVAILABLE

The final analysis of the figures took into account the suggested lag. The result of the final analysis showed a 73.2% correlation.

While one cannot expect a perfect correlation between figures in the social sciences, two factors could have lowered the actual correlation between the Presidential Popularity and the economic indicators. Both inconsistencies in the reporting of Gallop Poll data and current issues would influence the approval rating of the President. Gallop Poll did not report a Presidential Popularity figure for every month. During twenty-four months (25%) of the Eisenhower Administration, the Gallop Poll did not release popularity figures. This forced a "fudge factor" into the equation: for the months missing data, the preceding popularity figure was inserted. Current and domestic issues cause fluctuations in Presidential Popularity for which economic indicators cannot account. No tangible way exists to gauge the effects of current events and the amount they impact the President's popularity in a given month. Major issues that most likely artificially inflated or deflated President Eisenhower's popularity are the end of the Korean War, the sending of the National Guard to Little Rock to force the desegregation of schools, and the sending of troops to Lebanon.

Although the two sources of inconsistencies may skew the data on a month-to-month basis, the overall correlation of inflation and unemployment with Presidential popularity indicates that the two economic factors play a dominant role in a President's approval rating. The correlation was stronger than expected. The lag time for unemployment was expected, but the lack of a lag time for the correlation between inflation and Presidential popularity was not. In retrospect, the lack of a time lag makes sense: although monthly reports regarding the inflation rate and the unemployment rate are issued with a one month lag, an individual would have a better grasp on the current inflation rate because it affects their day-to-day lives. While an individual may not be able to state the inflation rate, he could tell you if it is rising or falling by increase or decrease in prices around him. An individual would have a harder time identifying with the unemployment rate unless he or she was actually unemployed; even so, an individual would have to rely on monthly reports for information about the unemployment rate.

A study of the modern Presidents, starting with Reagan (the other two-term President before Clinton was re-elected in 1996), may suggest a very different result. With the modern press and its coverage of the Presidency being much more extensive than it was at the time of Eisenhower's Presidency, Presidential popularity will probably deviate more frequently from the cycle resulting from a combination of inflation and unemployment.

It would not be surprising if a study of the most recent Presidents (Reagan, Bush, and Clinton) showed a lead time for presidential popularity as opposed to the lag discovered in this study of Eisenhower. Today experts are able to fairly accurately predict the state of the economy more than a month in advance, and it is this outlook, rather than the actual month's data, upon which the public today forms its opinion.

Regardless of the lead or lag time associated with presidential popularity and the inflation and unemployment rates, the fact that they are very closely tied cannot be ignored. While the 73.2% correlation that existed at the time of the Eisenhower administration may not exist today, a strong correlation between popularity and the economic factors can still be expected. To what extent, and exactly how the figures are related, are the questions that only further research can answer. This research reflects a preliminary stage in a much larger project.

Acknowledgments:

Many thanks to Dr. Donald White and the Mathematics Department at the University of Toledo for the statistical analysis assistance, as well as Dr. Cynthia DeSaint Victor and the University of Toledo Honors Program for their support. Special thanks to Dr. James Lindeen for all his guidance throughout this project.

Strategizing Advocacy: Theoretical Frameworks in Grass Roots Social Organization

"This country with its institutions, belongs to the people who inhabit it. Whenever they shall grow weary of the existing government, they can exercise their constitutional right of amending it, or their revolutionary right to dismember or overthrow it." Abraham Lincoln's First Inaugural

This paper seeks to educate those interested in advocacy and social movements about items related to the optimum time for movements to succeed, what elements must be present within an organization's mission including the dangers to be avoided and why it is so vitally important for our society to support and empower communities in their efforts toward positive social change. The focus of this paper is on the the common characteristics that resonate within all successful social movements. In May a summit headed by Colin Powell to include all of the living former presidents (Reagan will be represented by his wife), state and local officials, volunteers and young people will team up with corporate America to develop strategies for stimulating physical involvement and acitvism on the community level. It is at this level of society that social change truly happens, with a small group of people organizing and gaining power through empowering and bringing hope to the their communities. I intend to stress the importance of strategizing in order to maximize efforts and avoid the most common mistakes in advocacy by using the latest social organization theories and examples from a variety of social movements.

KEEPING DEMOCRACY ALIVE

In 1835 Alexis de Tocqueville's Democracy in America warned us of the dangers in a democracy if the people serve only the token position of voting for their representatives:

> It is vain to summon a people, which has been rendered so dependent on the central power, to choose from to time the representatives of that power; this rare and brief exercise of their free choice, however important it may be, will not prevent them from gradually losing the faculties of thinking, feeling and acting for themselves and thus gradually falling below the level of humanity . . . It is indeed, difficult to conceive how men who have entirely given up the habit of self-government should succeed in making a proper choice of those by whom they are to be governed; and no one will ever believe that a liberal, wise and energetic government can spring from the suffrages of a subservient people.

Tocqueville understood the importance of local community involvement and the price that a democracy will pay if the participants become disenfranchised from the people and policies that they are voting on. It has been said that one of the things'that sets us apart from the rest of the animal kingdom is our ability to hope. Tocqueville foresaw that lack of involvement will eventually result in apathy, a state of hopelessness.

The book The Quickening of America: Rebuilding our Nation, Remaking Our Lives by Francis Moore Lappe and Paul DuBois (1994) chronicles people from various demographies, (mostly working class, middle or low income) and their involvement in everything from labor organizations to environmental and educational causes and puts forth the idea of a new democracy in which the process of democracy becomes a core value and way of life. Women and men report a feeling of personal empowerment and both tangible and perceived improvement in the quality of their lives as a result. Lappe and DuBois assert that community involvement and the connectedness it brings fulfills natural social needs in our being producing a ripple effect of positive change spanning across the community and into our personal lives. Specifically improvements are reported in their book as an increase in confidence, job satisfaction (often the result of new or different employment), communication skills , and interpersonal relationships, perhaps most importantly relationships with their children. The authors explain the new democracy as an excitement and energy that is contagious in nature and thus sweeping across the nation in every corner of America . Involvement appears to bring hope, and with it the realization of power and personal satisfaction that permeates their lives.

Similarly, much has been said in recent years as to the positive affects of gardening. It seems that the process involved; preparing the soil, planting the seeds, adding water and fertilizer, tending to the upkeep and then being able to revel in the tiny agricultural miracle that results invokes a spirit of connectedness in those who participate in it and is now being used in schools nationwide. Studies involving the use of community or personal gardens have also been done in the poverty stricken inner city projects with one of the results being a decrease in violence and crime. When people have something that they are responsible for and something for them to be involved in, it breathes life into their community giving them the connection and commitment that apathy destroys. For when a community, defined here as any group of people with a common belief, cause or physical proximity, comes together and is able to function together as a more cohesive unit, they are then more effective at tackling issues and facilitating change on the global level. If people do not feel sufficiently involved in the democratic process and view it more as something outside of their lives, then their support for the process is going to be lacking as well. In being involved at some level of activism intermittently for the past ten years, I have found that those people participating in some kind community, civic, educational or political organization and working toward change feel much more empowered as a rule compared to those who have no involvement in the making of decisions that affect them. Apathetic comments like "It doesn't matter anyway" or "nothing *we* can do about it" are mere statements of powerlessness.

We have all heard the popular green phrase "Think Globally, Act Locally" which is indeed applicable to every area of advocacy. In my experience with a chapter of the National Organization of Women (NOW) and with starting a Young Democrats in northern California I saw that when young women became involved in these organizations a spark emerged that lit up a part of them they had not yet been in touch with. When young people begin to educate themselves and in turn begin to educate others on issues affecting them they stop feeling like things are happening *to them* and start believing that they *have the power to change* what is happening. Chapters of NOW have been holding an event for over twenty years called "Take Back the Night" while the venue varies across the country generally there is a march where women and children (men are now welcome as well) walk through the streets, parks and neighborhoods that are particularly dangerous in terms of rapes and assualts. Participants chant, sing and proclaim that the streets belong to them and they will not tolerate being victims of these crimes. One of the reasons for this is undoubtedly psychological. It is a known fact that rape is about power and generally a rapist carefully picks a victim based on someone they percieve as being powerless. By marching in Take Back the Night the women report a feeling of empowerment that becomes a part of who they are and lends itself to all aspects of their life. The march is particulary effective because it is a nationwide effort; communites create their own unique event raging from speakers in the community and law enforcement, self defense workshops and education about womens issues, but the global effect is the collective consciousness Take Back the Night creates.

Saul Alinsky addresses another aspect of this issue in the 1946 classic Reville for Radicals. Alinsky asserts that it is an ancient fallacy to assume that the laws make the men rather than the men make the laws (41.) A prime example according to Alinski is prohibition. When laws or policies are enacted that are contrary to the thinking of the majority of the people and/or are not supported by the majority of the people the process becomes vulnerable to failure, "The structure will always be no more than a reflection of its substance (40.)" Laws exist prohibiting sexual and physical assualt yet unless a community comes together to collectively take a firm stand against these atrocities and unless we educate and empower our communities to protect themselves the laws are not going to alleviate the problem.

GETTING STARTED

In looking at social causes over the past 100 years it is clear that there are certain movements that succeeded, gained momentum, sympathy for the cause or were simply set in motion due to some characteristic windows of opportunity that made the time for framing and/or executing efforts optimum. In his article "Culture and Social Movements" from the book New Social Movements (1995), Doug McAdam lists them as the following:

Ideological or Cultural Contradictions

Whenever a commonly held cultural belief is at odds with a widespread cultural practice and an event occurs to dramatize this discrepancy, this can serve to legitimize an otherwise non-tolerated protest activity. McAdam cites Sara Evans' (1980) belief that it is this climate that fueled the feminist movement of the 1960's and 1970's (40.)

Suddenly Imposed Grievances

Edward Walsh (1981) coined the phrase that is used by McAdam to explain the phenomena that follows in the wake of "dramatic, highly publicized and generally unexpected events-human made disasters, major court decisions, official violence-that increase public awareness of and opposition to previously accepted societal conditions." Prime contempoary examples of this phenomona would be what the Anita Hill testimony did for sexual harassment in the workplace and the rise in level of consciousness regarding spousal abuse in the wake of the Nicole Brown Simpson murder trial.

Dramatizations of System Vulnerability

Another culturally framed opportunity is any event or combination of events or processes that "highlight the vulnerability of one's political opponents." The *Brown v. Board of Education* US Supreme Court decision to ban racial segregation is used by McAdam as an example to how the civil rights movement was able to capitalize on the legal and political vulnerability of the system of southern segregation and accelerate the civil rights movement nationwide (41.)

The Availability of Master Frames

This cultural phenomena supports the ideas set forth earlier by Lappe and DuBois regarding the contagious nature of activism. McAdam asserts that "movements tend to cluster in time and space precisely because they are not independent of each other (McAdam and Rucht 1993)." McAdam goes on to theorize that in the 1960's there existed a "master protest frame" based in the momentum of the civil rights movements of which all others could be considered sub-groups. Applying the same theory today with regards to activism across college and university campuses, labor movements and grass roots efforts world wide I believe the current *human rights* movement to be the contemporary nucleus of the"master protest frame."

ORGANIZATION OF POWER

One of the most overlooked items in the framework of a grass roots organizing is the absence of an effective strategy, a business plan if you will that will serve as the organizations blueprint for success. Without a steadfast plan energies are wasted, efforts scattered and it is easy to deviate from the groups mission, that is if an effective mission could be established in the absence of a succinct strategy.

BEST COPY AVAILABLE

When definite strategies are not adopted it is easy for an organization to fall into a position of defense rather than the more desirable and powerful position of offense. When working primarily from the defense, a group is following someone else's agenda and is unable to take pro-active steps toward empowerment and realization of long-term goals. It is undoubtedly sometimes necessary to have a strong defense but for the most part defensive measures require short term fixes and thus gives rise to an organizations exhaustive state of "putting out fires". Whereas the strategy and implementation of a fire prevention program is long term and empowering for its constituents.

The development and implementation of an effective offensive strategy requires the organization to agree that the application and generation of power needs to "be controlled and applied for the attainment of the program or goal" (Alinsky 77.) In other words battles must be chosen wisely. Many grass roots organizations fall into a pattern of being unwilling to give up any part of its agenda in exchange for accomplishing bigger wins, because they do not want to give up anything to the "enemy." However, being flexible with regards to choosing what is the most important part of the ultimate mission provides bargaining power and leverage toward attaining a more significant victory. Also if an organization is unwillilng to compromise without a fight (which always drains precious resources) they are deemed not only unduly difficult but also less credible. Staying flexible allows for alternate and perhaps more feasible solutions that are not possible if a group is unwilling to participate at the proverbial or literal bargaining table while also building working relationships with those that they have the most to gain from.

It is not suggested however that something need always be given up nor does it mean to blindly accept compromises once an organization has built a working relationship with public officials, administrators, etc. In his book The Activists Handbook (1996), Randy Shaw address a powerful framework for dealing with elected officials, which can be applied to whomever an organization is working against, called the "fear and loathing approach (45.)" The technique is based on statements from Ernesto Cortez, Jr. of the Texas based Communities Organized for Public Service, regarding COPS's relationship to the local elected public officials;

> It's unfortunate that fear is the only way to get some positions to respect your power. They refuse to give you respect. They don't recognize your dignity. So we have to act in ways to get their attention. In some areas, what we have going is the amount of fear we can generate. We got where we are because people fear and loathe us (45.)"

This does not mean that it is not important to have any kind of working relationship with the officials. On the contrary, it means that when a relationship is developed it is important not to give up the power that the organization has gained by seeing these people as allies who are to be trusted and given blind concessions. Shaw points out that this is extremely critical in the case of a liberal or progressive official. If an organization begins to consider the official an ally or friend to the cause, the dangerous tendency is to not hold the person as accountable as an official who is non-sympathetic to the issues. This generally manifests into making excuses for the official (ie:"they are doing the best they can"), extending deadlines and no longer feeling comfortable with flexing the necessary political muscle so as not to offend the "ally." Having and adhering to a clear strategy will allow an organization to engage in dialogue and remain flexible while not compromising or deterring from the ultimate goals of the cause.

This same framework can be applied to fellow oranizations seen as allies. In a start up student political organization I was once a part of we had the opportunity as the associated student body to own a business that could have meant an incredible long term financial base for our organization and the many student clubs and organizations we would be giving financial assistance to. It so happened that one of these clubs was also interested in having the business. Problems arose for the student goverment when some members became very close to members of said club and felt that they did not want to step on anybody's toes or create any negative energy by putting the ultimate control of the business in the hands of the student goverment (who would then be able to filter any profit to all of the student clubs equally.) This resulted because there was not a clear agenda layed out as to our organizations financial goals and our responsibilties as the administrative body overseeing all student clubs and organizations. The result was not only a missed business opportunity but also a severe blow to the stregnth and credibility of our organization as a result of the internal power struggles that ensued. Again, problems that could have been easily avoided with a proper strategy from the onset.

CONCLUSION

The world is now at the dawning of a new century, experiencing technological and medical advances that never seemed possible one hundred years ago. Unfortunately our evolution in terms of compassion and activism is lacking in comparison. With the knowledge and technology currently available it seems incomprehensible that there are children still going to bed hungry and homeless; educational, economic or humanistic opportunities could be limited due to ones sex, ethnicity or religion; that natural resources including air and water are being destroyed and corrupted; and the list goes on. The hope for the new century lies in the activism of grass roots and community based social organizations and therefore in the awakening of the human spirit to feel individual power and responsibility to the delicate balance of all life on the planet. Saul Alinski said,"Logic tells us, "We'll believe it when we see it." But there is also the converse, faith. Faith, or belief in the people tells us, "*We'll see it when we believe it*" (235.)" It is not hard for people to become empowered for it is intrinsically inside all of us. Knowing when to get started, and what to do to make the most of available resources is the key. In closing I offer a quote from Randy Shaw, "By acting proactively and with tactical and strategic wisdom, social change activists can bring a degree of social and economic justice to the next century that has for too long been deferred (279.)"

Peering into the success of peer feedback: Understanding how feedback works in elementary-aged writers

Laura Angyal

Department of Psychology
Hamline University
1536 Hewitt
St. Paul, MN 55104

Faculty Advisor:

Matthew Olson

Peer feedback is an effective tool in the revision process of elementary school writers. Past research credited Piaget's theory of egocentrism for this success. It had been suggested that receiving feedback informs the writer. However, Vygotsky contends that children learn through developing inner-speech. Accordingly, the act of giving feedback is the instructional element of peer feedback. Participants included 77 fifth grade students at a suburban school. Students rewrote according to one of four peer feedback conditions (giving feedback/getting feedback, giving feedback/not getting feedback, not giving feedback/getting feedback, not giving feedback/not getting feedback). While statistical significance was not reached, students giving feedback/not getting feedback showed greater overall improvement.

BACKGROUND

Children work for years learning and practicing writing skills in an effort to gain writing proficiency. The process of writing is no doubt demanding of the young child who is still trying to master small motor skills and spelling (Berninger et al., 1992; Bereiter & Scardamalia, 1987). Teachers have addressed these limitations by allowing students to record their stories on tape or tell their stories to someone who transcribes them. Some teachers encourage inventive spelling to remedy the limitations of beginning spelling skills. Many children go on to become proficient writers; others seem stuck in this beginning stage. The remedial activities above may motivate children to write, but what facilitates development beyond these starter skills?

Barrs (1983) believes that it is important to view children as writers but to acknowledge the problems they encounter in writing as unique to their age. Olson (1990), in agreement with Barrs, identifies these problems as stages in development. Olson views one problem to be the inability of the young writer to understand audience awareness. While providing tools such as inventive spelling to aid the writer's restricted language skills, educators have also used techniques of revision to promote student understanding of the written language. These techniques include several types of feedback: teacher conferencing, teacher written comments, peer conferencing, self-monitoring and computer-generated feedback. Studies by Freedman (1987) and Olson found peer feedback to be the most effective method. It is not yet understood why this is true.

Researchers such as Olson (1990), who study peer feedback, point to Piaget's concept of egocentrism to help explain the limitations of student writing. Olson believes that peer feedback works because the child gains a sense of audience awareness from the other student. However researchers Liva, Fijalkow and Fijalkow (1994), studying the success of student task completion, found that children who verbally explain a task are more able to complete it. This test of Vygotsky's inner-speech theory suggest that learning comes from within the child rather than from an audience effect. Researchers who support Piaget's theory believe that the information given through feedback informs the writer. Yet, applying Vygotsky's theory of inner-speech to the process of revision, peer feedback is successful because the child, in giving feedback, learns inner-speech which will regulate revision.

Peer feedback is recognized as an effective tool in teaching writing skills to elementary-aged children. It is the intent of this study to determine why feedback works. It is proposed that in giving feedback, the student learns inner-speech prompts about writing. These prompts inform the student about his or her own writing ambiguities. Based on Vygotsky's theory that learning language occurs through inner-speech development, it is predicted that students who give feedback will show greater improvement in writing than students who do not give feedback.

METHODS

Participants

Seventy-seven suburban grade school students, aged ten to eleven, participated in this project. The students were in one of four fifth grade Language Arts classes. The classes were randomly assigned to one of four groups. Permission to work with the students and collect data was obtained from the school and parents.

Materials

Instruction of all students included reading the folktale Strega Nona. A web sheet was provided for each student to help organize the story. Editing was modeled on an overhead projector.

Design and Procedure

Classes were randomly assigned to one of four conditions. One class of students, assigned to the exchange group, gave and received feedback from a peer before rewriting. A second class of students assigned to the giving group gave feedback to other students but rewrote their stories without receiving feedback. A third group of students assigned to the receiving group got feedback from other students but did not give feedback before rewriting. A fourth group of Students assigned to the control group neither gave or received feedback before rewriting.

All students received 45 minutes of writing instruction, three times a week for two weeks. Instruction included information about writing. The information discussed was the same for each group with the exception of references to peer feedback during editing. Students in the control group received the same information regarding the kinds of questions asked during editing, but instruction did not specifically address peer questioning as a component of editing. Class discussion and modeling provided a base for the writing. The day before the data was collected, students were told that they would be writing about an event in their own lives. This allowed for variations in composing styles. Each student wrote one story in a 45 minute time period and revised it two days later.

Students in the control group rewrote their stories without feedback. Students in the exchange group were randomly paired. One student from each pair was given their partner's story to read and discuss with the partner for 15 minutes. The partner whose story had just been critiqued then became the editor, reading the other student's paper and providing feedback for 15 minutes. Both students then revised their stories. Students in the receiving group were paired with students from the giving group. One student assigned to the giving group was given their partner's story to read. The story was read and the reader provided feedback for 15 minutes. The students receiving feedback then left for another class. The students giving feedback then edited their own stories without further discussion.

Scoring

The stories and their revisions were compared for the number and type of improvements made. The groups were then compared for differences in improvements between conditions. Scoring the stories included five points each for character-clarity, plot development, setting development, continuity and conclusion. These points were then combined to create a content score. Spelling, grammar, and punctuation errors were counted and divided from the total word count giving a "words per error" score. The content score was then added to the words per error score to create an overall performance score. To determine improvement from first write to rewrite, each student's revised story was scored similarly. Five additional points were given for each piece of information added during the revision process which provided further development or clarification. A words per error score was also calculated for the revised version. These scores were combined, as in the first write, for an overall performance score. Scores in content, words per error and overall performance from the first write were subtracted from the content, words per error, and overall performance scores of the edited story to create word error improvement, content improvement and overall improvement scores. Scores were compared within subjects from first write to rewrite and between subjects by condition.

RESULTS

Analysis included a 2 x 2 ANOVA to determine if there were significant differences in the means on the measure of writing improvement between giving feedback and getting feedback in three areas: words per error, content and overall improvement. Results showed there was no significant difference between the students who gave feedback and those who received feedback

714

BEST COPY AVAILABLE

for the conditions of words per error improvement, F (2, 76) = .212, p = .810, content improvement, F (2, 76) = .780, p = .462, or overall improvement, F (2, 76) = .098, p = .907. Paired-samples t-tests determined there was significant improvement in words per error for two groups, give only and give and get. Paired t-tests also indicated significant content improvement for all groups (see Tables 1, 2).

Independent-samples t-tests indicated a significant difference in homogeneity between the give only and give and get conditions. The Levene's Test for Equality of Variances suggest significant levels of unequality for words per error and overall performance (p = .04). This may be due to a difference in sample size compounded by overall small sample sizes.

Table 1: Mean Scores of Words-per-Error for All Students

Group	n	First Write	Rewrite
Control	20	15.71	19.10
Give/Get	18	22.28	26.93*
Give only	18	17.19	27.63**
Get only	21	15.08	22.31

* significant improvement from first write to rewrite p < .05.
** significant improvement from first write to rewrite p < .01.

Table 2: Mean Scores for Content for All Students

Group	n	First Write	Rewrite
Control	20	16.50	20.25**
Give/Get	18	13.61	15.56*
Give only	18	5.46	6.03*
Get only	21	14.05	17.86**

* significant improvement from first write to rewrite p < .05
** significant improvement from first write to rewrite p < .01

DISCUSSION

The results of this study indicate that the type of feedback condition did not significantly influence the student's editing ability. In most instances, however, there was significant improvement within each group. Significance was not reached in only two cases, words per error of the control group and of the get feedback group. The fact that significant improvement was not reached in all groups for words per error is interesting. It appeared that students easily recognized the spelling and grammar errors in both their own writings and the writings of other students. In observing students during the feedback stage, it was noted that students tended to focus on spelling errors. This was also evidenced in their editing notations. This could be explained because this area of writing is concrete (words are either spelled correctly or incorrectly). However, the results suggest that this type of correction benefited from the act of giving feedback.

It was hypothesized that the process of editing another's work educated the student in the questioning skills necessary to edit his or her own work in a similar manner. Past researchers suggested that detecting areas of ambiguity required an objectivity or knowledge that only an outsider possessed. All groups demonstrated significant improvement in content from first write to revision. This may be due to the instruction students received in an effort to equalize their past educational experiences. In all classes, ambiguities and clarification in writing were discussed and modeled. Furthermore, students appeared genuinely interested in this questioning process.

It is interesting to note that although there was not a significant difference between groups for content improvement, results showed a tendency for students in the getting and not giving group and the control group to do better than the giving only group or giving and getting group. This is hard to understand. If these results could be broken apart, it may be suggested that the success of students receiving feedback supports Olson's (1990) theory, that egocentrism limits the student's ability to detect ambiguities. However to suggest this, students in the giving and getting group should have also done better than students in the giving only group. This was not the case, the students who gave and received feedback showed the least improvement.

To explain the success of the control group, it is necessary to consider the unique situation that arose. It was later discovered that the control group was a class in which two-thirds of the students worked at below grade level. This may have effected their level of performance. In a sense, they may have benefited more from instruction that the other classes due to their limited knowledge going into the project. They may have had a greater learning window. The constant modeling and use of visuals may have optimized their ability to understand the writing and the editing process. Their success may also be attributed to Hull's (1987) findings that poor writers, who are often poor readers, concentrate on comprehension as they try to understand text.

The results from the words per error scores suggest that it is more beneficial to give feedback than to get feedback. However, as with the content improvement scores, students who gave and got feedback did poorly. These students seemed as engaged as the others during instruction. Perhaps in the process of two-way editing the students lost their focus, however, this did not seem to be the case in observing their editing discussions.

Further research will need to include long-term instruction to override students' past education in editing practices. Allowing long-term instruction will control for students overly focusing on the areas to be measured, different learning styles and previous learning experiences.

ACKNOWLEDGEMENTS

The author wishes to thank Matthew Olson, Phd., R. Kim Guenther, Phd., and Charles LaBounty, Phd., from Hamline University for the support and endless feedback on this project. Without the assistance of Donna Nelson this project would not have been possible.

Research has shown that the acculturation process is a source of stress for minority students leading to interpersonal stress and adjustment problems. For the Mexican-American population it is important to further investigate what impacts these experiences. The purpose of this study was to examine (a) the impact of acculturation type and gender on social support and (b) the impact of acculturation type, gender, and social support on stress among Mexican-American adolescents ($N=113$). Data analysis consisted of two ANCOVAs, one for each research question, which yielded significant results for gender on social support and social support on stress. The results have implications for intervention related to acculturation and social support skills. In addition, preventive measures can be used to decrease stress for students at risk.

BACKGROUND

U. S. Hispanics are quickly becoming the largest minority, and much research on acculturation and the effects of acculturation with this group has been done. Acculturation has been defined in many ways but all suggest that it is a process of change experienced by members of a minority group toward the adoption of the majority group's culture (Negy & Woods, 1992).

Most studies on acculturation have focused on adults, but in recent years a shift to examining culture change among younger populations has occurred. Primarily studies on youth investigate the impact of acculturation on health issues like drug use and pregnancy (Barrett, Joe, & Simpson, 1991; Reynoso, Felice & Shragg, 1993).

Other topics investigated have been the relation of acculturation and values in first generation Mexican-Americans (Domino and Acosta, 1987). The authors found that those showing a higher degree of acculturation ranked values similarly to rankings of those by Anglo subjects. Szapocznik, Scopetta, and Tillman (1977) found that factors that affected acculturation in a sample of Cuban immigrant families included variables such as length of exposure to the host culture, age, and gender. The authors reported that rates of acculturation differ among females and males with males acculturating faster. In addition, the process of acculturation affects family members differently. The process becomes accelerated in the children and "retarded" in the parents (Szapocznik et al., 1977).

Padilla (1980) described the process of acculturation as consisting of three stages. The first stage is contact. Contact occurs when someone from one culture enters another. Typically for children and adolescents contact occurs in the schools. The second stage is conflict. It is in this stage that and individual's response to the contact is examined. Conflict may occur if differences in world views, culture, and traditions between the individual and the new culture exist. The final stage is adjustment in the form of acceptance, reaction, or withdrawal. Students resolve conflict by either withdrawing from, reacting to, or accepting the new culture however for children and adolescents how they respond to conflict is not made independent of others. Their choices can be restricted by adults at home, school, or in the community.

The measurement of acculturation in children, adolescents, and adults has been the focus of many studies as well (Franco, 1983; Collier, 1985; Szapocznik, 1978; Mendoza, 1989; Olmedo, Martinez, & Martinez, 1978). Less research has been done on the impact of stressful changes on the development of adolescents. Factors that are associated with stress or stressful events in children and adolescents include the child's own characteristics (i.e. Type A behavior), factors inside/outside the home, parental fights/separation, academic retainment, the child's biopsychosocial competencies (including social support), and the pleasantness of events (Hawkins, 1981).

Research has also shown that the experiences at school are a source of stress for young people, impacting their homework, family, friends, as well as their physical or emotional well-being. Minority children may experience higher levels of school stress because of the differences in family ecology and school environment, leading to problems developing a sense of belonging and social support (Munsch & Wampler, 1993).

The process of acculturation itself has been found to be a potential source of stress called acculturative stress (Padilla, 1980), possibly impacting ethnic adolescents. Seeking and attaining acculturation instigates interpersonal stress in ethnic minorities and is accompanied by more adjustment problems (deDomanico, Crawford, & De Wolfe, 1994). A Mexican-American adolescent's adjustment can either be enhanced or inhibited by the acculturating process (deAnda & Becerra, 1984). Further, Williams and Berry (1991) emphasize the effect of acculturative stress:

> The concept of acculturative stress refers to one kind of stress, that in which the stressors are identified as having their source in the process of acculturation, often resulting in a particular set of stress behaviors that include anxiety, depression, feelings of marginality and alienation, heightened psychosomatic symptoms, and identity confusion. (p. 634)

These authors found that the degree of acculturative stress experienced depends on many factors: mode of acculturation, phase of acculturation, way in which majority culture exerts its acculturative influences, socioeconomic status, social support, acceptance/prestige of ones group in acculturation settings, and psychological variables (i.e. social support). Ramirez and Hosch (1991) also showed evidence that acculturative stress affected family functioning.

It has been suggested that bicultural (acculturating to the majority culture while keeping values from your own culture as well) students are better able to mediate acculturative stress in culturally uncertain situations (DeDomanico et al., 1994). DeDomanico et al (1994) also found that bicultural identity is related to better adjustment. As a result for minority children, being bicultural is more beneficial as far as social support and adapting are concerned. Another study by Montgomery (1992) with a sample of students from South Texas found "that as one moves through the generations, one becomes more bicultural/blended and comfortable and less bicultural/blended and alienated...over generations, subjects lose their enthusiasm for their Anglo preference, and indicated a more Mexican preference" (p. 217). As can be seen in these studies being bicultural was related to better coping in adolescents. However, a study on acculturation and adjustment by Moyerman and Forman (1992) failed to find a consistent unidirectional effect of acculturation on adjustment.

Support networks traditionally in the form of family ("familismo"), are important in the Mexican-American culture. Acculturation has an effect on this support system for adolescents in families and evidence has been contradictory. In a study by Ramirez and Hosch (1991) with families from a bicultural community it was found that encouraging biculturalism is important in minimizing detrimental effects of acculturation among these families with adolescents. Another study with a sample consisting of African-Americans, White, and Mexican-American adolescents making the transition to 7th grade showed that minority students involved relatives (parents and siblings) more often in their support networks than Whites in regard to social support. The extended family may be an important resource for minority youth as they explore their cultural heritage (Phinney & Chavira, 1992).

Researchers have failed to research fully the impact of acculturation type (from very Mexican-oriented to very Anglo-oriented) on stress and social support. Exploring these factors is important because they have been found to be interrelated, in particular social support on stress. It is believed that acculturation type and gender impact social support, and that all three of these variables influence stress. Thus this study attempts to find (a) the impact of acculturation type and gender on social support and (b) the impact of acculturation type, gender, and social support have on stress among Mexican-American adolescents.

METHOD

Participants

Hispanic students in grades 9 through 12 from schools in the Midwest and Southwest were asked to participate. Schools selected for this study were those with a high percentage of minority students. All Mexican-American students in the various schools were sent permission letters and those who returned them were selected for the project.

The identification of the students and their parents were compared. The majority of students (77%) identified as either Mexican-American (46%) or Mexican (31%). The majority of parent's (81%) identified as Mexican-American or Mexican of which 55% identified as Mexican.

Instruments

Acculturation Rating Scale for Mexican-Americans (ARSMA). The ARSMA (Cuéllar, Harris, & Jasso, 1980) consists of twenty items which measures acculturation at five different levels: Type 1, very Mexicano; Type 2, more Mexican oriented; Type 3, bicultural; Type 4, more Anglo oriented; and Type 5, Anglo oriented. The ARSMA is based on four factors: language familiarity, usage, and language; individual ethnic identity and generation; reading, writing, general cultural heritage and exposure; and ethnic interaction. The instrument possesses adequate reliability and validity.

Social, Attitudinal, Familial, Environmental (SAFE) Acculturative Stress Scale. The SAFE Acculturative Stress Scale (Padilla, 1986) consists 60 items rating from 1 (Not Stressful) to 5 (Extremely Stressful). Stressors among immigrant and later generation multi-cultural populations such as Mexican-Americans are assessed by the SAFE. Internal reliability for the SAFE revealed a coefficient of .89.

BEST COPY AVAILABLE

The Interpersonal Support Evaluation List (ISEL) The ISEL (Cohen & Hoberman, 1983) consists of 5 types of social support based on the support-buffering model: total support, belonging support, self-esteem support, appraisal support, and tangible support. Currently, the ISEL has been changed to a questionnaire containing 40 items with four response choices ranging from Definitely True to Probably False. There is no reliability and validity available for this format.

Procedure

Once students returned their permission letters they were given a consent form. The instruments were administered as a group or individually. The questionnaires were administered by a designee at the sites.

Analysis

ANCOVAs were conducted to assess the influence of acculturation type and gender on social support and to estimate the effect of acculturation type, gender, and social support on stress.

RESULTS

Data Analysis

The first ANCOVA addressed the impact of acculturation type and gender on social support. The results of the ANCOVA revealed significant findings for gender. This suggests that differences in social support are accounted for by differences in gender.

Table 1: ANCOVA Results for Acculturation Type and Gender on Social Support*

Source	Df	SS	MS	Fvalue	Pr > F
Gender	1	1.20	1.20	6.50	0.01***
Error	110	20.28	0.18		
Corrected Total	112	21.69			

ISEL measures social support* ***significant

Results of the second ANCOVA measuring the influence of acculturation type, gender, and social support on stress revealed significance for social support. This suggests that social support influences the amount of stress.

Table 2: ANCOVA Results for Acculturation Type, Gender, and Social Support* on Stress

Source	Df	SS	MS	Fvalue	Pr > F
ISEL*	1	3.88	3.88	7.30	0.008***
Error	108	57.41	0.53		
Corrected Total	112	63.81			

* ISEL measures social support *** significant

Descriptive analysis indicated that a greater proportion of adolescents described themselves as Type 2 - Bicultural, more Mexican-oriented (55%). Within this group, a greater percentage rated their stress level as low. However, in comparison with different acculturation type adolescents those defined as Type 2 exhibited the greatest stress. Further, of 65 students ranked in the low stress level, 57% were students in Type 2. Mean analysis of gender and stress showed slightly higher stress among males than females (mean =2.6, S.D.=.79 vs. mean=2.53, S.D.=.79). On the other hand the women's mean on social support was higher than the men's (mean=3.17, S.D.=.43 vs mean=2.95, S.D.=.42).

DISCUSSION

In recent years an impetus to investigate academic success among Mexican-Americans has emerged. However, few studies have examined acculturation and psychological factors such as stress and social support among Mexican-American adolescents. In this study the purpose was to examine the impact of acculturation type and gender on social support and the effects of acculturation type, gender, and social support on stress. ANCOVAs were used to determine significance between the variables of interest. Descriptive analysis provided further examination of results.

The first ANCOVA revealed significant results for gender and social support. This suggests that significant gender differences exist, with women rating their support as higher. Results of the second ANCOVA on stress indicated significance for social support, suggesting that support makes a difference on how stress is mediated. Although not significant, descriptive analysis revealed that adolescents in Type 2 (Bicultural, Mexican-Oriented) showed the greatest and the least stress compared to others in differing acculturation types.

The results of this study support previous findings in relation to gender differences. Males showed slightly greater stress than women. However social support appeared to moderate these results. Women showed more social support than men. Given that men showed greater stress while women showed more social support, the data do not clarify whether women were still highly stressed. It could be that because of strong social support, women's stress was not perceived as high. Women have been shown to adapt easier, subsequently reducing stress levels (Garcia-Vázquez, Vázquez, & Huang, In Press). At the same time the females in the present study were at Type 2 suggesting a dynamic process of acculturation.

Although these results support previous findings, it was interesting to find that Type 2 adolescents were found to have the lowest and highest stress levels. Perhaps adolescents were at differing levels of acculturating, leading some to perceive more stress while others less. Further research could examine what contributes to stress when adolescents are at Type 2.

Implications

The information gained from this study can help in implementing academic and psychological interventions. For adolescents in the process of acculturation, it will be important to provide social support to ease the stress associated with the process. This will be especially important since stress affects social, emotional, and academic endeavors. Of particular importance would be to provide support for males, who may be experiencing greater sources of stress. As a result, preventive measures could be implemented to reduce stress for adolescents at risk. Counseling programs, peer support, and academic strategies are examples of preventive measures. At the same time, it will be critical to provide assistance for adolescents experiencing high stress. Since the females in this study seemed to have greater social support, examining the types of coping strategies they utilized could assist other adolescents.

Limitations

Limitations to this study may have influenced the findings. The sample size (N=113) and restriction of range on acculturation may have limited the significance of the study. In addition, the scope of the study did not address the relation between stress and social support. Teasing out their interaction could clarify their impact on other factors. Another limitation is the instruments employed. While these questionnaires are reliable and often used on children and adolescents they are not normed on adolescents. Because of these limitations further research with these variables is necessary, especially among Mexican-American adolescents. Limitations aside, the strength of the study lies in helping the professional understand the lives of Mexican-American adolescents.

Physiological Responses to Racist Stressors Among African-American College Students

Jamar Barnes, John A. Oliver, Foye Smith

Departments of Psychology
Morehouse College
830 Westview Dr. S.W.
Atlanta, GA 30314

Faculty Advisor:

Vernessa R. Clark

The of the study was to investigate differences in cardiovascular responses to black on black racism and white on black racism. Thirty black male and female college students participated. The participants watched two scenes on videotape: a black person being harassed by another black person, and a black person being harassed by a white person. It was hypothesized that cardiovascular responses would be greater during the scenes depicting white on black racism. A t-test was used to detect differences in cardiovascular reactivity between African-American males and females. Significant gender differences were found in heart rate responses to both the white on black racism scene, t (40)= 5.54, p=.000, and the black on black racism scene, t (40)= 4.92, p=.000. A second significant finding was the diastolic blood pressure measurement to the white on black racism scene, t (37)= 2.00, p=.053. This study will help identify which type of racial stressors produce the greatest physiological responses to stress.

INTRODUCTION

Racism is the experience of ethnic prejudice or discrimination (Clark, Anderson & Clark, unpublished manuscript). Two main types of racism are attitudinal and behavioral (Yetman, 1985). Both forms of racism are debilitating stressors for many African-Americans (Lawrence, 1983). Attitudinal racism refer to attitudes or ways of thinking that discriminate against individuals or groups because of their phenotypic characteristics. Behavioral racism is referred to as any act of discrimination that denies an individual or group equitable treatment (Yetman, 1985).

Because of the difficulty of measuring physiological changes to racism in a natural environment, researchers have utilized the laboratory to obtain results (Clark, Anderson & Clark, unpublished manuscript). For example, Sutherland and Harrell (1986-1987) found that imagining racially noxious and fearful scenes produced an increase in facial muscle activity in women. When compared to resting measures, imagining these scenes also resulted in increases in heart rate (Sutherland & Harrell, 1986-1987). In examining the interaction of racism and gender, it was found that males showed higher cardiovascular reactivity to racist stressors than females (Stone, Dembroski, Costa & MacDougall, 1989).

The present study investigated gender differences in cardiovascular reactivity to black on black racism and white on black racism. It was hypothesized that males would have greater cardiovascular reactivity to both racist scenes than females.

METHOD

Participants

Twenty-five females from Spelman College in Atlanta, Georgia and twenty-five males from Morehouse College in Atlanta, Georgia volunteered to participate in the study. The students were between the ages of 18-26 and were screened for cardiovascular disorders.

Apparatuses

The Medex NCCOM3 impedance cardiograph and microcomputer system were used to assess heart rate. To obtain these measures, eight electrodes were placed on the neck and both sides of the body near the area of the xiphisternum. Blood pressure was taken by the Ohmeda Fina Pres Model 2300 blood pressure monitor. The psychological stressors used in the experiment were two racist scenes and one neutral scene on videotape. One of the racist scenes depicted African-American students being harassed by white students (white on black scene). The other racist scene depicted an African-American soldier of higher rank harassing another African-American soldier of lesser rank because of his race (black on black scene). The neutral scene, which served as a control, showed a rabbit running through a field at sunset. Prior to the experiment, each individual was given a screening form and an informed consent form. The screening form identified medical conditions that excluded the individual from participating in the study. The informed consent form was administered after an explanation of the nature of the study was given.

Procedure

Upon entrance into the participant room, each participant was given a screening form and a consent form. After the presentation of each scene, the participants were asked to reflect on what they saw. They were asked to put themselves in the position of the victim and speak to the authority figure. Heart rate and blood pressure were measured as the participants viewed the three scenes. Heart rate and blood pressure measurements were taken prior to the stimulus, during the stimulus, while the participant reflected on the stimulus, and while the participant recovered from the stimulus. Each period lasted eighty seconds and measurements were taken every twenty seconds. The mean averages of measurements were used in the analyses of the results.

RESULTS

A t-test was used to detect differences in cardiovascular reactivity between African- American males and females. Significant gender differences were found in heart rate responses to both the white on black racism scene, t (40)= 5.54, p=.000, and the black on black racism scene, t (40)= 4.92, p=.000, with females having higher cardiovascular responses than males. Females also had higher diastolic blood pressure measurements than males in response to the white on black racism scene, t (37)= 2.00, p=.053. In addition, a t-test was used to detect heart rate and blood pressure differences between the baseline and stimulus periods between males and females. These findings were not significant.

Figure 1

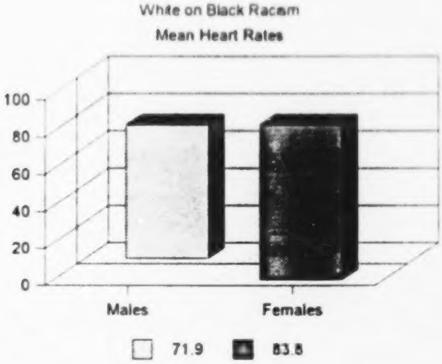

Figure 2

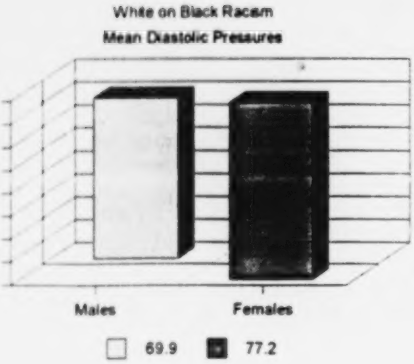

Figure 3

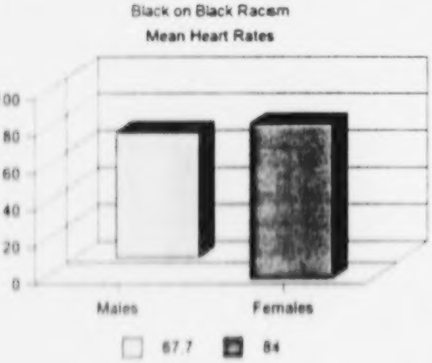

DISCUSSION

The hypothesis that males would have greater cardiovascular responses to the scenes than females was not supported. Females had higher blood pressure and heart rate activity than males. These findings contradicted research results found by Stone et al., (1989) who found that males had greater cardiovascular reactivity than females. One possible difference in the two studies is the nature of the stressor used. The present study used racist scenes as a stressor. Females were more responsive to such overt acts of racism than their male counterparts, possibly because women are socialized to express their feelings where as males are socialized to suppress their feelings.

It is believed that the present study will be helpful in identifying stressors that produce the greatest physiological responses. Once they are identified, researchers may be able to predict what stressors are most detrimental to a person's overall health and well being.

Gender Differences in Perceptions of Marital Infidelity: Sexual Versus Emotional Cheating

Anne-Marie Bartos and Allison D'Auteuil

Department of Psychology
Hendrix College
1600 Washington
Conway, AR 72032

Faculty Advisor:

Dr. Ralph J. McKenna

A study of martial infidelity was conducted in which undergraduate students at a small liberal arts college read passages containing sexual and emotional cheating behavior. Participants rated the degree of fault attributed to each party: the cheater, noncheater, and third-party. Differences in degree of fault for each party and between passages, the gender of the party found at fault compared to the gender of the participants (p<.003), and past infidelity of participants were explored. Evolutionary psychology was utilized to explain the differences found. Uxoricide, wife killing, is linked to this study as a consequence of martial infidelity.

BACKGROUND

Cheating, infidelity, and unfaithfulness are three synonymous terms for one behavior. But is it one behavior? A student can cheat on a test (Enker, 1987), a friend can be disloyal, and a spouse can be unfaithful (Peck, 1975). Studying infidelity can cover such a wide range of behaviors and conditions that it is necessary to limit the categorical terms (Thompson, 1984). This study encompasses extramarital infidelity.

Green, Lee and Lustig (1974) examine "five common motives that patients give when asked why they were unfaithful": sexual frustration, curiosity, feelings of revenge or boredom, and a need for acceptance and recognition from another person. Without the freedom within a relationship to have contact with the outside world and other persons (Rhyner, 1984) these five motives can cause excessive jealousy (Peck, 1975). "Jealousy is defined as an emotional state that is aroused by a perceived threat to a valued relationship or position and motivates behavior aimed at countering the threat. Jealousy is 'sexual' if the valued relationship is sexual" (Buss, Larsen, Westen, and Semmelroth, 1992; Daly, Wilson, and Weghorst, 1982, p. 11; Salovey, 1991; White and Mullen, 1989). It includes emotions such as fear and anger. The threat of a loss of love and all that the love encompasses feeds the fear to the point of jealousy (Izard, 1991). These motivations along with jealousy can lead to infidelity (Green, Lee, and Lustig, 1974).

Just as love is not limited to sexual attraction (Izard, 1991), infidelity is not limited to sexual encounters. It has only been in the last twenty years that the nonsexual components have received attention (Roscoe, Cavanaugh, and Kennedy, 1988; Weis and Slosmeric, 1981). The nonsexual component being "deep emotional attachment" (Buss, Larsen, Westen, and Semmelroth), commonly known as love. Thompson (1984) examined three types of marital infidelity: "(1) emotional (love), not sexual; (2) sexual (intercourse), not emotional; and (3) both emotional(love) and sexual (intercourse) in married subjects. Roscoe et al (1988) expanded the study of infidelity to include dating behavior.

Buss et al (1992) studied male and female adaptive problems faced over evolutionary history in mating contexts. The two evolutionary psychological issues discussed at great lengths are male sexual infidelity and female commitment infidelity in cultures where males invest heavily in children. "[Sixty percent] of the males sampled reported greater distress [than females] over potential sexual infidelity; in contrast, only 17% of females sampled chose that option, with 83% reporting that they would experience greater distress over a partner's emotional attachment to a rival". The evolutionary argument contends that males are more inclined to commit sexual acts of infidelity for population reasons, where as females are less likely to engage in sexual acts of infidelity for fear of "losing a man's investment" (Buss et al, 1992). In light of the Buss conclusion that females are more likely to be distressed with emotional infidelity and males with sexual infidelity because of the investment factors involved, one question remains unanswered.

Who is to blame? Mathes and Verstraete (1993) list two possibilities: the beloved and the third party, reasoning that the beloved has betrayed the individual with the third party. But is the individual completely free of responsibility? Does the relationship have any of the five motive qualities already discussed? The need for acceptance and recognition is great. If the individual is not receiving that attention from the beloved is he or she wrong for seeking it elsewhere?

It is the first hypothesis that males will find sexual extramarital infidelity by both sexes more upsetting than emotional extramarital infidelity, whereas females will find emotional extramarital infidelity more upsetting. A second hypothesis is that all subjects will view the female's role in the passage, be it the individual, the beloved, or the third party, as more at fault. The independent variables are the gender of the subjects, and the passages read. The dependent variables are which form of infidelity, sexual versus emotional, subjects find more upsetting; which party is found more at fault-individual (cheater), beloved (non-cheater), or third party; and the sex of the person found more at fault.

METHOD

Forty-eight participants, 23 males and 25 females were recruited from Hendrix College social psychology and anthropology classes to participate in this study. The first group consisted of 22 participants, while the second group contained 26. Two passages approximately one page each were used in each group. The first passage described a man who cheated on a woman with another woman for strictly sexual reasons. Cheating for strictly sexual reasons implies that the partner is only sexually attracted and feels no emotional bond with the third party. The second passage described a woman who cheated emotionally on a man with another man. Emotional cheating indicates that there is some type of emotional attachment felt between the third party and the cheating partner, although nothing sexual (kissing, intercourse, etc.) occurs between them. These two passages were used in the second condition also, although the genders in each passage were reversed. In all four passages, the couples are married to indicate a strong commitment between the two people.

A questionnaire consisting of ten questions was used to measure which type of cheating was considered more upsetting by the participants. It also assessed the degree of fault attributed to each party (cheater, non-cheater, or third party). An item read, "How much at fault do you perceive Jody (a character in the sexual cheating story) to be?" A 5-point Likert scale was used to measure the dependent variables (1=less at fault, 5=more at fault).

PROCEDURE

Testing occurred in two sessions. In the first session, participants met in a classroom and were instructed to read two passages, one sexual cheating passage and one emotional cheating passage. The genders of the cheater, noncheater, and third party varied among the passages read so the participants did not read about a male or female cheating in both passages. Each pair of passages were stapled alternately, to control for any ordering effect that may occur. After the participants finished reading both passages, a 10-item questionnaire was distributed. After all participants completed and returned the questionnaire to the experimenter, debriefing occurred. The second session was identical to the first.

RESULTS

A 2 X 2 factorial ANOVA was utilized to compare the type of cheating to the gender of the participant.

Table 1: Participants Perception of Sexual and Emotional Cheating on a 5-point Likert Scale (1=less upsetting, 5=more upsetting)

	TYPE OF CHEATING	
GENDER OF PARTICIPANT	SEXUAL	EMOTIONAL
MALE	4.870	3.000
FEMALE	4.920	2.920

Sexual cheating was found to be more upsetting than emotional cheating by both male and female participants, $p < .001$. This result supported only the first part of the hypothesis stating that males will find sexual cheating to be more upsetting than emotional cheating.

The second hypothesis, that females would be blamed more than their male counterpart in each passage, was not significant. However, in the sexual cheating passage, the female cheater, noncheater, and third-party tended to be blamed more than the male counterpart by an average of 1.327 points. In regard to the emotional cheating passage, the attribution of fault varied among males and females.

Another ANOVA measuring the interaction between gender of the participant and gender of the third-party was found to be statistically significant, $p < .003$.

Table 2: Fault Attributed to the Third-Party on a 5-point Likert Scale (1=less at fault, 5=more at fault)

	GENDER OF CHEATER	
GENDER OF PARTICIPANT	MALE	FEMALE
MALE	3.917	2.455
FEMALE	2.538	3.250

The male participant blamed the male third-party more than the female third-party, whereas the female participant blamed the female third-party more than the male third-party.

The next factorial ANOVA analyzed the gender of the participant, the participant's past experience of whether he or she sexually and/or emotionally cheated, and his or her opinion on how upsetting sexual cheating is.

Table 3: Participants Perception of Sexual Cheating on a 5-point Likert Scale (1=less upsetting, 5=more upsetting)

	Emotionally Cheated?		Sexually Cheated?	
GENDER OF PARTICIPANT	YES	NO	YES	NO
MALE	4.800	5.000	4.333	4.950
FEMALE	4.900	5.000	5.000	4.905

Although significant results were not found, some general trends were shown. Females tend to view sexual cheating as more upsetting than males do. Participants who had emotionally cheated before, do not view sexual cheating as upsetting as participants who had not emotionally cheated previously. Males who had sexually cheated do not view sexual cheating as upsetting as males who had not previously sexually cheated. Females who had sexually cheated view sexual cheating as more upsetting than females who had not sexually cheated previously.

Also, the 7 participants that admit to sexual cheating, viewed sexual cheating as less upsetting ($X = 4.714$) than the 41 participants who had not cheated sexually in the past ($X = 4.927$). The 37 participants that had emotionally cheated in the past considered sexual cheating as less upsetting ($X = 4.87$) than the 41 participants who had not emotionally cheated previously ($X = 4.927$).

The next ANOVA was similar to the previous one, except the opinion of the participant was on how upsetting emotional cheating was. There was a significant main effect for participants who have cheated previously, $p < .01$.

Table 4: Participants Perception of Emotional Cheating on a 5-point Likert Scale (1=less upsetting, 5=more upsetting)

	Emotionally Cheated?		Sexually Cheated?	
GENDER OF PARTICIPANT	YES	NO	YES	NO
MALE	2.533	3.875	2.667	3.050
FEMALE	2.700	3.800	1.750	3.143

Participants who had cheated emotionally or sexually, viewed emotional cheating as less upsetting than participants who had not emotionally cheated in the past. In general, participants who have not cheated previously (sexually or emotionally), view emotional cheating as more upsetting than those who have cheated (sexually or emotionally), although these results are not significant.

DISCUSSION

Results support the hypothesis that males find sexual infidelity worse than emotional infidelity. However, results also reveal females find sexual worse than emotional infidelity, which is contrary to the hypothesis. The previous research on the topic of cheating behavior, including unfaithfulness and infidelity, gave no indication that females would find sexual worse than emotional infidelity. This result may have been due to the assumption that all participants have the same understanding of emotional infidelity. The passages were meant to exemplify what emotional and sexual infidelity actually means so that the participants would have a basis to provide ratings on the questionnaire.

The trend discovered in the sexual passage, showing that the female character in each role was blamed more than her male counterpart, can be explained through gender stereotypes. In regard to the cheating character, historically it is accepted that males will have more than one sexual partner. They are said to have to "sow their wild oats". If this sowing does not take place before the marriage, then it is likely to happen after the bond. The infidelity behavior is often excused because "a man can not control his desires". Females on the other hand are expected to be with one and only one male for an entire lifetime. According to the norm, women should be virgins when married and remain faithful to the husband. In this sense it is only natural to ask: Who can blame the male for cheating? Is it not in his nature?

In a study by Wiggins and Ledener (1984), the relationship between the third-party and the noncheater was explored. In evolutionary theory it is often found that the third-party is looked down upon by members of the same sex because he or she is seen as "hurting one's own kind" (Shackelford and Buss, 1996). When a man cheats on a woman the third-party female has betrayed her gender by "stealing" a taken man. Participants relating to and having the same gender as the noncheater, view the third party as betraying their gender. This research supports the present study's findings in that the male participants blamed the male third-party more, whereas female participants blamed the female third-party more.

Another article by Wilson and Daley (1996) provide explanations for uxoricide, wife killing, that directly relates to the result of males blaming the male third-party more than the female third-party. Wifely infidelity is viewed as an exceptional provocation, likely to elicit a violent rage. Battered women nominate jealousy as the most frequent motive for their husbands assaults. According to the evolutionary theory, adaptive problems men face include the risk of losing their wife, a valuable reproductive source, to a rival and the risk of directing paternal investments to another man's child (Wilson and Daley, 1996).

In light of the past and present research, infidelity is a very obscure concept. It is very difficult to test participants since there are so many different degrees and levels of cheating. One way to elicit an honest response from participants may be to ask them to imagine themselves in a cheating situation. Infidelity is a subject that should be investigated so that one can understand the reasoning behind the action.

Barbara Beaver

The purpose of this study was to determine if a link may be found between abuse history, fear of negative evaluation, and negative self-statements concerning heterosocial interaction. Participants were 59 female and 39 male college students from a semi-rural midwestern college. Correlational analyses were done for both genders between measures of childhood and adolescent abuse history, fear of negative evaluation, and the use of positive vs. negative self-statements concerning social interaction. Positive correlations were obtained between the scale for sexual abuse and fear of negative evaluation, and between the scale for sexual abuse and the negative self-statement scale in the female group. T-tests revealed a significant difference between genders for total scores on the Child Abuse and Trauma Scale (CAT; Sanders & Becker-Lausen, 1995) and for the negative home environment/neglect subscale of the CAT. Implications suggest that a woman with a prior history of sexual abuse may be more vulnerable during social interaction with an abusive man and therefore may also be more vulnerable to involvement in an abusive relationship. Findings of a significant difference between genders on the CAT, specifically in the area of negative home environment/neglect imply that girls suffer a higher level of abuse in this area than do boys.

BACKGROUND

The three major areas of child and adolescent abuse; those of neglect and verbal abuse, physical abuse, and sexual abuse, are likely to occur in the same family and this general parental abusiveness is associated with somatization, anxiety, depression, interpersonal sensitivity, obsessive-compulsive behavior, dissociation and suicidal ideation (Briere & Runtz, 1988). Furthermore, establishing trust in others may be difficult for children who have not received psychological help after an abuse incident (Kinard, 1982). Other negative psychological consequences of abuse are feelings of vulnerability and loss of control, guilt, self blame, and a heightened sense of fear and anxiety which can become generalized (Goodman, Koss, & Russo, 1993). Female victims of sexual abuse have reported insecurities concerning sexual attractiveness, lowered sexual self esteem, and negative feelings about men (Koss &Harvey, 1991; McCahill, Meyer, & Fischman, 1979). A history of abuse in childhood can have a damaging and enduring effect on personality functioning (Van der Kolk, 1987; 1988). Distortions of cognition such as a belief in one's own badness, and affect responses such as a hypersensitivity to potential rejection and feelings of humiliation and shame often exist in women with abuse history (Brown, 1987).

The desire to be accepted and to avoid rejection has long been viewed as a central human motive (Horney, 1937; Maslow, 1987; Baumeister &Leary, 1995). Concern with the unfavorable evaluation of others has been illustrated in a number of social situations including those involving conformity, prosocial behavior, self-presentation, self-serving attributions, social anxiety, self-handicapping, attitude change, compliance, and social facilitation (Schlenker, 1980). People who are highly concerned with negative evaluation are more likely to behave in ways that avoid the possibility of unfavorable evaluations, and thus be more responsive to evaluative situations (Leary, 1983). The Fear of Negative Evaluation Scale (FNE; Watson & Friend, 1969), was developed to determine the degree to which people experience apprehension at the prospect of being evaluated negatively. Individuals with high levels of fear of negative evaluation attempt to avoid potentially threatening social comparison information to a greater degree than those with low levels of fear of negative evaluation (Friend & Gilbert, 1973), and indicate they feel worse about negative evaluations than do people with little fear of negative evaluation (Smith & Sarason, 1975). Individuals with high levels of fear of negative evaluation also prefer to be in a positive asymmetrical relationship - being liked by another more than one likes the other - rather than a reciprocal relationship (Smith & Campbell, 1973). These

BEST COPY AVAILABLE

individuals are also more concerned with making a good impression on others and try harder to do so during face to face conversations (Leary, 1983). In addition, those who score high on fearof negative evaluation measures also score high on measures of social approval seeking (Watson & Friend, 1969).

A significant number of adolescents experience anxiety and dissatisfaction with their social interactions, most notably with the opposite sex, and seek counseling more often for difficulties in heterosexual relationships than for any other reason (Martinson &Zerface, 1970). There are three existing models used to explain the etiology and maintenance of these social difficulties (Curran, 1977). This study follows the third model for which there is strong evidence stating that heterosocial problems are due to cognitive distortions. These cognitive distortions include the presence of irrational beliefs (Goldfried & Sobocinski, 1975), overly negative self-evaluations of social performance (Clark & Arkowitz, 1975; Glasgow & Arkowitz, 1975), negative self-statements (Cacioppo, Glass, & Merluzzi, 1979), excessively high standards for performance (Bandura, 1969), selective attention and memory for positive versus negative information about oneself and social performance (O'Banion & Arkowitz, 1977), and pathological patterns of attribution for social success and failure (Miller & Arkowitz, 1977).

As previously stated, victims of abuse show interpersonal sensitivity (Briere & Runtz, 1988), difficulty establishing trust (Kinard, 1982), generalized fear and anxiety (Goodman et al., 1993), damage to personality function (Van der Kolk, 1987; 1988), distortion of cognitions and a hypersensitivity to rejection (Brown,1987), and female victims of sexual abuse report insecurities about their own sexual attractiveness and have negative feelings about men (Koss & Harvey, 1991; McCahill et al., 1979). It was expected that childhood and adolescent abuse history would be positively correlated with the dimensions of fear of negative evaluation and negative self-statements concerning heterosocial interaction.

Furthermore, it has been suggested that women may have more reason to fear negative evaluation from others to the extent that they hold lower social power than men, and thus may be more dependent on others for approval because disapproval and rejection often entails material as well as social losses (Miller, 1995). Therefore, it was also expected that women would report a greater level of fear of negative evaluation than men.

METHOD

Participants. Participants were 59 female and 39 male college students from a semi-rural midwestern college. Participants ranged in age from 18 to 24 years (97%), and were from freshman psychology classes. Racial/ethnic composition was primarily white (98%).

Materials and Apparatus. The Child Abuse and Trauma Scale (CAT, Sanders & Becker-Lausen, 1995). The CAT is 38 item, 5 point Likert type scale designed to give a quantitative index of the frequency and extent of various types of maltreatment in childhood and adolescence.

The Brief Negative Evaluation Scale (BFNE, Leary, 1983). The BFNE is a 12 item, 5 point Likert type scale. It is a brief version of the original 30 item true-false scale; the Fear of Negative Evaluation scale (FNE, Watson & Friend, 1969), that is designed to measure the degree to which people experience apprehension at the prospect of being evaluated negatively.

The Social Interaction Self-Statement Test (SISST, Merluzzi, Biever,& Larsen, 1982). The SISST is a 30 item, 5 point Likert type scale designed to assess self-statements concerning heterosocial interactions which contains 15 positive (facilitative) and 15 negative (inhibitory) self-statements yielding a separate score for positive self-statements and a separate score for negative self-statements.

Procedure. Participants completed the three scales in same gender groups of 5 to 20 individuals. The order of questionnaires was varied to reduce influence effects from one scale to another. All three scales contain written self-directed instructions.

RESULTS

Abuse History and Fear of Negative Evaluation. A significant positive correlation was found between the CAT-subscale for sexual abuse and the BFNE: $r=.30$, $p<.05$, but only in the female group. Contrary to what was expected, overall CAT scores indicating the frequency and extent of maltreatment in childhood and adolescence did not correlate positively with fear of negative evaluation for either gender.

Abuse History and Self-Statements Concerning Social Interaction. A significant positive correlation between the CAT-subscale for sexual abuse and the negative self-statement scale of the SISST was found again only in the female group: $r=.34$, $p<.01$

Fear of Negative Evaluation and Self Statements Concerning Social Interaction. In the female group a high positive correlation was found between the BFNE and negative self-statement scale of the SISST: r=.71, p<.01, and conversely a negative correlation between the BFNE and the positive self-statement scale of the SISST: r=.54, p<.01. In the male group, a significant correlation was also found between the BFNE and the negative self-statement scale of the SISST: r=.43, p<.01.

Gender Differences. It was expected that women would score higher in fear of negative evaluation than men, however t-tests were not significant: t(96)=1.80, p<.074. T-tests did reveal a significant difference between genders for total scores on the CAT: t(96)=2.41, p<.018, and a highly significant difference between genders for the negative home environment/neglect subscale of the CAT: t(96)=2.82, p<.006.

DISCUSSION

Abuse History and Fear of Negative Evaluation. Findings suggest a link between a history of sexual abuse in women, specifically childhood and/or adolescent history of sexual abuse and an adult apprehension for being evaluated negatively. Implications relating to attraction for a woman who has been sexually abused in childhood, may simply be manifested in a propensity for this woman to find it difficult to initiate a conversation with a prospective partner because she is overly concerned with negative evaluation. Leary (1983) has found that people who fear negative evaluation are more likely to behave in ways that avoid the possibility of unfavorable evaluations, and thus be more responsive to such situations. A woman who has been sexually abused in childhood, fearing negative evaluation, may not only avoid initiating a conversation with a prospective partner, but may avoid any interaction until her fears are diminished.

Establishing trust becomes difficult for those who have suffered abuse (Kinard, 1982). Female victims of abuse report insecurities concerning sexual attractiveness, lowered sexual self esteem, and negative feelings about men (Koss & Harvey, 1991; McCahill et al., 1979). These reported insecurities help to explain in part why findings show a connection between fear of negative evaluation and childhood and adolescent sexual abuse. Individuals with high levels of fear of negative evaluation prefer to be in a relationship in which one is liked by another more than one likes the other (Smith & Campbell, 1973). This may be due to a need for constant approval rising out of a lack of trust and lowered sexual self esteem.

Watson and Friend (1969) found that individuals who feared negative evaluation not only avoided disapproval but sought approval. A jealous, controlling behavior has been found to be characteristic of abusive men (Downey & Feldman, 1996; Walker, 1984). It is speculated that this controlling behavior may play a role early on at the attraction level of dating or mate selection, in that an abusive man could use flattery or repeated reassurance to gain the trust of a woman who has been a victim of sexual abuse in childhood. It has often been reported by battered women that their abusive partner approached like a whirlwind claiming love at first sight and using flattery like "you're the only person I could ever talk to" or "I've never felt loved like this by anyone before" (Walker, 1984).

Abuse History and Self-Statements Concerning Heterosocial Interaction. A significant positive correlation was found between the measure of sexual abuse history and negative self-statements concerning heterosocial interaction, also again only in the female group. This finding suggests a link between childhood and adolescent abuse in women and negative self-statements or negative thoughts and expectations about heterosocial interaction. Distortions of cognitions such as a belief in one's own badness, and feelings of humiliation and shame have been found in women with abuse history (Brown, 1987). There is sufficient evidence that heterosocial problems are due to cognitive distortions, including negative self-statements (Cacioppo, Glass, & Merluzzi, 1979). The presence of a positive correlation between childhood and adolescent sexual abuse and negative self-statements concerning heterosocial interaction further supports the proposed connection between prior abuse and worry about negative outcomes during interaction. The aspect of "expecting the worst" lends support to the model of a woman with sexual abuse history being avoidant of initiating a heterosocial interaction on the basis that she expects that she will be rejected. In this scenario she may wait to be approached, reasoning that this aproachment is a sign of approval by the prospective partner. It is possible that an abusive man recognizes this weakness as an opportunity to dominate in - or have control of - the relationship.

Fear of Negative Evaluation and Self Statements Concerning Social Interaction. Positive correlations were found between fear of negative evaluation and negative self-statements for both

BEST COPY AVAILABLE

genders, implying that one dimension may accompany the other. There was a high positive correlation between these two dimensions for the female group as well as a negative correlation between fear of negative evaluation and positive self-statements concerning heterosocial interaction. The later was absent in the male group. These findings show a stronger correlation between fear of negative evaluation and negative self-statements concerning heterosocial interaction for women.

Gender Differences. Although analysis approached significance, it cannot be generally stated according to the results of this study that women do indeed have an overall greater fear of negative evaluation than do men. It is significant to note that although women and men showed a comparable level of sexual abuse history, there were only relationships found between sexual abuse history and fear of negative evaluation and between sexual abuse history and negative cognitions during heterosocial interaction for women, supporting previous research that childhood and adolescent abuse does not produce the same effects in girls that it does in boys (Hughes, H.M. & Barad, S.J., 1983).

Important results of this study are the highly significant differences between genders for total scores on the CAT, specifically demonstrated by the negative home environment/neglect subscale of the CAT. The mean CAT score for women was more than double that of the men and the negative home atmosphere/neglect subscale mean score for women was over 33% higher than for men. These findings imply that girls suffer a higher level of negative home atmosphere and neglect than do boys. Negative home atmosphere is generally defined as the general negativity of the home atmosphere including loneliness and neglect (Sanders & Becker-Lausen, 1995). Questions in this scale include areas such as caring for one's self prior to being old enough, childhood stress levels as reported by the participants, parental verbal abuse and parental drug and alcohol abuse, and time spent left alone as a child.

Results that show women reporting higher levels of negative home environment/neglect may be reflected in part by the model of Dr. Laura Brown (1992) who has proposed the construct of Abuse/Oppression Artifact Disorder in understanding the presence and threat of trauma in the lives of girls and women. This model suggests in part that all women living in a culture (such as North America) where there is a high rate of sexual abuse and assault, are at risk to the effects of trauma. In this study the men reported similar levels of sexual abuse in childhood and adolescence to the women. With little doubt, as young men mature their increase in body size and strength may serve to lessen the fear of sexual abuse and assault in adulthood, a fear that does not diminish for most women. One of the most crippling definitions of psychic pain or trauma in response to abuse and oppression is that these responses are pathological. Effects such as these should be seen as natural and understandable responses to the trauma produced by the abuse and oppression of women. Brown (1992) also suggests that the effects of abuse and oppression do not necessarily need to come from overtly violent acts, but can also result from what she terms "violence to the soul and spirit". This is a factor that would appear to exist as a threat to girls and women of our society, as demonstrated in this study by the reported higher levels of negative home atmosphere and neglect of girls and young women than of boys and young men.

Limitations and Directions for Future Research. Generalizability of this study is limited by its' racial and culturally homogeneous groups. However, this constraint may offer additional support of the horrific prevalence of abuse of girls and young women in our society, and serves to further debunk the myth that abuse occurs only in the lower classes. Also important is that this study was limited to heterosocial design largely due to the design of the measures used. Further research is needed to compare homosocial interactions in relation to abuse history.

Vernessa R. Clark

The current study examined differences in anger expression, hostility, and John Henryism among African-American and Caucasian female college students. It was hypothesized that African-American women would score high on the anger-out subscale of the Spielberger Anger Expression Scale and Caucasian women would score high on the anger-in subscale. In addition, it was also hypothesized that there would be no difference in hostility and John Henryism between the African-American and Caucasian participants. Also, a positive correlation between John Henryism, hostility, and baseline cardiovascular responses was predicted. Nine African-American females from Spelman College and eight Caucasian females from Smith College participated in the present study. Each participant was given the Spielberger Anger Expression Scale, the Cook and Medley Hostility Scale, and the John Henryism Scale for Active Coping. Baseline measures of heart rate and blood pressure were taken prior to the administration of the scales. A t-test was used to examine ethnic group differences in scores on all coping scales. There were no significant differences between African-American and Caucasian on any of the coping questionnaires. In addition, a Pearson correlation test was used to examine the relationship between baseline cardiovascular responses and the coping questionnaires. None of the correlations was significant.

INTRODUCTION

The importance of coping in determining the impact of psychological stress has been recognized in past research. The current study examined the relationship between three coping strategies (anger expression, hostility, and John Henryism) and baseline cardiovascular reactivity in African-American and Caucasian female college students. A brief review of the literature that examines the three coping styles is presented below.

Anger Expression

Anger expression is defined as an indicator of one's behavior toward others. This construct determines whether individuals suppress their anger (anger-in), outwardly express their anger (anger-out), or control both the experience and expression of anger (anger-control) (Spielberger, Johnson, Russell, Crane, Jacobs & Worden, 1985). Research has shown that individuals exhibiting the anger-in style tend to have higher blood pressure when placed in anger provoking situations (Armstead, Lawler, Gorden, Cross & Gibbons, 1989). Gentry, Chesney, Gary, Hall, and Harburg (1982) found that females with high levels of anger in, had higher systolic blood pressures than females with anger-out expression.

Hostility

Hostility is a personality construct seen in people who are easily angered, have high levels of resentment and irritability, and are cynical and mistrusting of others (Smith & Frohm, 1990). Suarez & Williams (1990) reported that individuals with high hostility scores responded to an anger-arousing laboratory challenge with greater cardiovascular responses than individuals with low hostility scores. Scherwitz, Perkins, Chesney, and Hughes (1991) found that young Black males with limited education had the highest scores on the Cook and Medley Hostility Scale, whereas older educated white females had the lowest scores. Similar findings were reported by Barefoot, Peterson, Dahlstrom, and Seigler (1991), who found higher hostility scores in non-White men and subjects of low socioeconomic status.

John Henryism

John Henryism is a behavior pattern used to describe individuals with a predisposition to actively cope with psychological stressors of everyday life (James, Keenen, Strogartz, Browning & Garrett, 1992). Found most often in Black men, high levels of John Henryism have been correlated with high blood pressure (James, Strogatz, Wing & Ramsey, 1987). Black men who obtained high scores on John Henryism, yet had limited education, had higher diastolic blood pressures than men who had median scores on both the scale and blood pressure. Many studies have shown that there were no significant differences in John Henryism between black men and women (eg. James, Hartnett & Kalsbeek, 1983). Yet a recent study conducted by Jackson (1994) showed that women scored higher on the John Henryism scale than men.

The purpose of this study was to investigate the relationship of coping strategies, blood pressure and heart rate in African-American and Caucasian female college students. It was hypothesized that African-American women would score higher on the anger-out subscale of the Spielberger Anger Expression Scale than Caucasian women. It was also hypothesized that Caucasian participants would score higher on the anger-in subscale of the Spielberger Anger Expression Scale than African-American women. It was also hypothesized that there would be no difference in hostility and John Henryism between the African-American and Caucasian participants. Also, there would be a positive correlation between John Henryism, hostility and baseline cardiovascular responses in both ethnic groups.

METHOD

Participants

Twenty females from Spelman College in Atlanta, Georgia and twenty females from Smith College in Northampton, Massachusetts volunteered to participate in the study. The students were between the ages of 18-26 and were screened for cardiovascular disorders.

Questionnaires and Forms

Prior to the experiment, each individual was given a screening form and an informed consent form. The screening form identified medical conditions that excluded the individual from participating in the study. The informed consent form was administered after an explanation of the nature of the study was given. The Cook and Medley Hostility Scale (Cook & Medley, 1954) - a measure of hostility, the Spielberger Anger Expression Scale (Spielberger, Johnson, Russell, Crane, Jacobs & Worden, 1985) - a measure of expressed anger vs suppressed anger coping strategies, and the John Henryism Scale for Active Coping (James, Keenen, Strogartz, Browning & Garrett, 1992)- a measure of motivation toward success in the face of adverse circumstances, were used.

Apparatuses

The Medex NCCOM3 cardiac impedance cardiograph and microcomputer system were used to assess heart rate. To obtain these measures, eight electrodes were placed on the neck and both sides of the body near the area of the xiphisternum. All signals were read into the cardiovascular monitor and interfaced to a Radio Shack TSR 80 portable computer. Digital printouts of the cardiac measures were obtained through a Hewlett Packard printer. Blood pressure was taken by the Ohmeda Fina Pres Model 2300 blood pressure monitor.

Procedure

Upon entrance of the laboratory, each participant was given a screening form and an informed consent form. After all questions were answered, the recording equipment was attached. Baseline measures were taken for three minutes as the participants sat in a comfortable recliner. After this rest period, the participants were given the coping questionnaires.

BEST COPY AVAILABLE

RESULTS

A t-test was used to examine ethnic group differences in scores on the Cook and Medley Hostility Scale, the John Henryism Scale for Active Coping and the anger-out and anger-in sub-scales of the Spielberger Anger Expression Scale. There were no significant differences between African-Americans and Caucasians on any of the coping questionnaires. The finding was expected for hostility and John Henryism but not for the anger-in or anger-out sub-scales of the Spielberger Anger Expression Scale.

A Pearson Correlation test was used to examine the relationship between hostility, John Henryism, anger-in, anger-out, anger control, overall anger expression and baseline cardiovascular responses. None of the correlations was significant. (See Table 1)

DISCUSSION

The present study did not support the hypothesis that African-Americans and Caucasians express their anger differently. The results of this study indicate that there are no ethnic group differences in anger expression when using college females. This finding is supported by Dimsdale, Pierce, Schoenfeld, Brown, Zusman, and Grahman (1986) who found significant differences between anger and systolic blood pressure among black and white men, but not for women.

The hypothesis stating that there would be no difference in hostility and John Henryism between African-American and Caucasian female college students was supported by our data as well as other studies (eg. Suarez & Williams, 1990). The results of this study did not support the hypothesis that there would be a positive correlation between John Henryism, hostility and baseline cardiovascular responses. There was no significant correlation between these factors possibly because of the limitations in data analysis. Seventeen subjects were analyzed in the correlation. A complete data analysis of all forty subjects needs to be completed before a definite conclusion can be made.

Table 1

Correlations Among Anger Expression John Henryism, Hostility and Baseline Cardiovascular Responses

	HR BASE	SYS BASE	DIA BASE
HOS	- .1256	.1194	.0691
JH	.1702	.0320	.1385
AIN	.0836	- .2385	- .2378

Wendy L. Hill

ABSTRACT

The effects of methysergide and ritanserin, two similar 5-HT2 antagonists, on the behaviors of adult, male zebra finches were investigated after acute intraperitoneal injection (0.5, 1.0, 2.0 mg/kg and 0.3, 1.0 mg/kg respectively). Behaviors of each bird (n=9) were examined for the hour post-injection in an aviary using ethological procedures. Surprisingly, the particpants' aggressive displays did not vary among the conditions for either antagonist. The percentage of time spent inactive, however, was significantly greater following methysergide administrations, and a similar pattern was seen for ritanserin injections. These findings of decreased aggression and increased inactivity contrast with some findings from other mammals.

BACKGROUND

Much of the research that has manipulated serotonin levels in animal species thus far has led to notable changes in aggressive behavior. However, this research has studied a single behavior in isolation rather than exploring how the entire behavioral profile of an animal might have been affected. Wingfield (1978) has introduced a field perspective to study the role of physiological processes on behavior, which results in greater ecological validity. Not only do the results determine whether or not the manipulation caused a particular behavior, the general effects on the animal's behavioral repertoire can be explored. Therefore, it is relevant to take the behavioral repertoire of an animal and categorize behaviors to develop a conceptional understanding of aggression.

Studies by Moyer (1968, as cited in Feldman & Quenzer, 1984) have shown that aggression has a specific neurochemical basis. Reduced levels of serotonin (also known as 5-HT) lead to an increase in aggressive behavior, while increases in 5-HT lead to a decrease (Eichelman, 1987). Most of this work has been conducted on mammals (although see Buchanan, Shrier, & Hill, 1994). Few studies have examined the effects of serotonin antagonists, agents that block the effects of 5-HT, on the complete behavioral profile of passerines, more specifically, zebra finches (*Taeniopygia guttata*). The following two experiments explored the effects of two serotonin antagonists, methysergide and ritanserin, on the wide variety of behaviors unique to zebra finches. It was expected that these 5-HT antagonists would increase their aggressive behaviors.

EXPERIMENT 1: METHYSERGIDE ADMINISTRATION

Methysergide is a serotonin antagonist that specifically blocks the subtype-2 receptors of 5-HT. The effects of four different doses on the behavioral repertoire of male zebra finches were examined.

METHOD

Zebra finches are sexually dimorphic, Australian grassfinches of the family Estrildidae. Like other estrildids, they form life-long pair bonds, with both sexes participating in nest construction, incubation, brooding, and feeding of the altricial young (Burley, Krantzberg, & Radman, 1982). In nature, zebra finches breed in loose colonies typically in low shrubs.

Nine, adult male zebra finches were used as participants for this study. Each participant was banded with a numbered aluminum leg band and a unique combination of three color bands. All bands were of colors previously demonstrated to be neutral in attractiveness by Burley *et al.* (1982). Prior to experimentation, they were housed in unisexual groups. Each male was then introduced into an aviary (2.7m x 2.7m) with their respective female partner, creating a total of nine pairs. An additional three pairs were also released into the aviary, but did not receive treatment. All birds were kept on a regime of ad libitum food, water, and nesting materials. A 14L:10D photoperiod was maintained throughout the study, with light onset at 0800h. Nests were checked daily between 0900 and 1200 hours. At this time, the number of eggs, hatchlings, and fledglings were recorded at each active nest. Daily maintenance of the aviary was also performed during this time.

The aviary contained three solid walls and a galvanized metal screen, with a standard-size door for entry. Inside the aviary, three PVC pipes, 7.5 cm in diameter, were situated 1.5 m apart and ran the height of the room. Five dowels were placed through each pipe, creating ten perches per pipe. Thirty wicker baskets were positioned and numbered at the ends of perches as sites for nests. Perches were 45 cm long and spaced at heights from 0.9 to 2.1 meters off the floor. A food station was located on the wall across from each pipe which included water troughs, a hanging feeder with perches, a metal food trough, a cuttlebone, and a bin filled with cotton for nest building.

Methysergide was purchased from the Sigma Chemical Company and was combined with 0.9% saline vehicle. The vehicle alone was administered when the birds received the control condition. Disposable tuberculin syringes (1 cc) and needles (26 3/8) were used for the i.p. injections. Timex stopwatches were used to time the recovery and observation periods. A Radio Shack tape recorder was used to record all observations. Wire mesh cages (3.7 m x 3.7 m x 4.9 m) individually housed participants following injection.

The participants were given a three day habituation period following their release into the aviary. The study consisted of a random presentation of four drug conditions to all nine birds: three distinct dosages of methysergide (0.5 mg/kg, 1.0 mg/kg, 2.0 mg/kg) and a saline (control) condition (0.0 mg/kg). Conditions were randomly labeled A, B, C, or D, and the experimenter was blind to the dosage being delivered. Two to three recuperation days following drug administration were allotted to all participants. Therefore, the complete injection phase consisted of four days of afternoon observation, spread over an eleven-day time period. Most of the treatment conditions were administered during the pre-laying phase of the birds' reproductive cycle (61%) and no participants had advanced past the incubation phase during testing.

At the start of each test period, three birds were selected at random and tested sequentially. The first bird to be observed on an injection day was removed from the aviary at its designated time and given an i.p. injection of the drug condition specified. The birds was then placed in the wire mesh cage for a period of 15 minutes, prior to returning to the aviary. Following re-release into the aviary, a five minute habituation period elapsed before observations were recorded for an hour. The date, time, coding of condition injected, participant's number and color code, and all behavioral observations were recorded into the recorder. After the observations were completed, this procedure was then repeated for the remaining two finches selected.

Audio tapes were transcribed upon completion of observations. Using the continuous sampling method, all behaviors were recorded to determine their rate of occurrence. In addition, the instantaneous sampling method was also employed in order to record the specific behavior at the end of one-minute intervals; these data enabled the calculation of the proportion of time spent in 12 behavioral categories: aggression, courtship, communication, inactivity, ingestion, locomotion, nesting, maintenance, incubation, social preening, defense, and miscellaneous behaviors. The data were then collated to examine the behavioral changes across the four treatment phases. A Friedman's two-way analysis of variance by ranks was used to examine possible differences among the treatment conditions for the categories of behaviors. Each category was analyzed separately using the rates of behaviors, derived from continuous sampling, and using the percentage of time spent in the behavior, assessed by instantaneous sampling. If a Friedman's ANOVA was significant, follow-up tests were conducted using the Wilcoxin's nonparametric test ($p<0.05$).

RESULTS

Courtship and communication behaviors were so infrequent that they were not subject to statistical analysis. Initially, the participants displayed a wide variety of behaviors. However, as the dosage of methysergide increased, this variation diminished, and the time spent inactive significantly increased ($X^2r = 14.20$, $df=3$, $p<0.05$), so that there was significantly more inactivity under the two highest doses.

Correspondingly, the rate of locomotor activity varied significantly among the treatment conditions ($X^2r = 9.83$, $df=3$, $p<0.05$). The average number of bouts per hour of

BEST COPY AVAILABLE

locomotor behavior during the saline condition was significantly greater than the number of bouts during either the 0.5 mg/kg or 1.0 mg/kg dosage condition. The mean rates of behaviors for each of the 12 behavioral categories as a function of two methysergide doses (0.0 mg/kg (control) and 2.0 mg/kg (highest dose)) are presented below in Figure 1.

The percentage of time spent in maintenance behaviors as well as the rate of maintenance activity also varied significantly among the treatment conditions ($X^2r = 12.63$, df=3, $p<0.05$, $X^2r = 13.53$, df=3, $p<0.05$ respectively). An average of 11.30% of the participants' time was spent on maintenance behaviors when injected with the control, however, this value decreased significantly to 1.48% in the highest dose of methysergide (2.0 mg/kg) and to 0.37% in the 1.0 mg/kg dose. Similarly, the average rate of maintenance behavior was 63.33 bouts per hour during the saline condition, but following the highest dose of methysergide the behavior decreased significantly to an average of 24.78 bouts per hour (Figure 1).

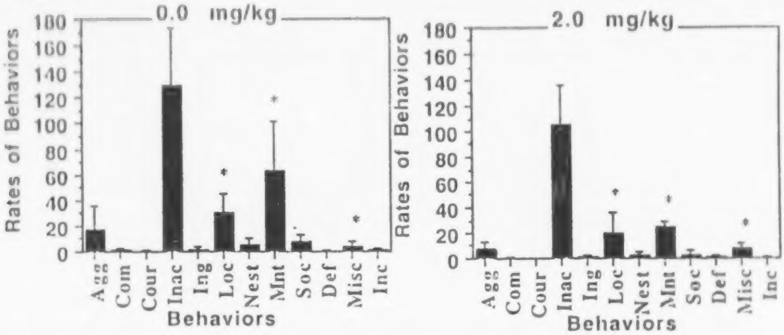

Figure 1. Mean rates of behaviors for each of the 12 behavioral categories (aggression, communication, courtship, inactivity, ingestion, locomotion, nesting, maintenance, social preening, defense, miscellaneous behaviors, and incubation) as a function of methysergide dose (0.0 mg/kg (control) and 2.0 mg/kg (highest dose)).

A similar pattern among the treatment conditions was seen in the rates of nesting behaviors ($X^2r = 6.70$, df=3, $p=0.08$). The average number of bouts of nesting during the saline condition was twice the number of bouts during both the 0.5 mg/kg and 2.0 mg/kg conditions, and four times the number of bouts during the 1.0 mg/kg condition (Figure 1). The percentage of time spent nesting, however, did not vary significantly among the conditions ($X^2r = 2.30$, df=3, $p>0.05$).

The rate of miscellaneous behaviors varied significantly among the conditions ($X^2r = 10.03$, df=3, $p<0.05$). These behaviors consisted of twitching and a response that resembled coughing and were often associated with the methysergide injections.

DISCUSSION

The results of this first experiment suggest that methysergide is an activity depressant in zebra finches. The treatment conditions yielded no significant differences for aggressive behaviors and therefore the initial hypothesis is not supported.

Previous experiments have demonstrated that serotonin antagonists like methysergide usually decrease the frequency of sleep (inactivity) (Feldman & Quenzer, 1984). In this experiment, the percentage of time spent inactive varied significantly among the treatment conditions, showing an increase rather than a decrease in inactive behavior following methysergide exposure. Furthermore, the range of doses of methysergide employed here all showed similar behavioral effects, in that they decreased activity and social interaction among the birds. Thus, no linear effect was obtained for a dose-response curve.

EXPERIMENT 2: RITANSERIN ADMINISTRATION

In order to be confident that the results of Experiment 1 are due to the specific neurological effects of methysergide and the physiological makeup of finches, a similar but more potent serotonin antagonist was utilized. Ritanserin slowly dissociates from the same 5-HT_2 receptor sites as methysergide (Leysen, Van Gompel, Gommeren, Woestenborghs, &

Janssen, 1986)

Previous research on mammals using ethological procedures has demonstrated that ritanserin increases aggression. Gao & Cutler (1993) found that the aggressive behaviors of mice increased after administration of ritanserin, as did digging and investigative behaviors. In addition, Sommerfelt & Ursin (1993) determined that administration of ritanserin increased waking and decreased slow wave sleep in cats.

If the same patterns of behaviors occur in the finches from ritanserin administration as they did from methysergide, it is more likely that serotonin is, in fact, the neurotransmitter responsible.

METHOD

Eight of the nine male participants from Experiment 1 were used for the second experiment. Although this species is known to form life-long pair bonds (Burley *et al.*, 1982), one male participant had lost his mate to a non-participating male. Therefore, this male was used for Experiment 2. All other procedures were the same as discussed in Experiment 1, except three drug conditions were randomly presented: two distinct dosages of ritanserin (0.3 mg/kg and 1.0 mg/kg) and a saline condition (0.0 mg/kg).

RESULTS

More than half of the trials occurred during the pre-laying period of the reproductive cycle, with the others happening during either egg-laying or incubation. Behaviors such as communication, courtship, social preening, and defense were infrequent, and thus, were not subject to statistical analysis. Aggression, incubation, and miscellaneous behaviors were somewhat infrequent, but analyses indicated no significant differences between the three drug conditions for any of these behavioral categories.

Figure 2 (below) illustrates the mean percentage of time spent in each of the 12 behavioral categories as a function of two ritanserin doses, 0.0 mg/kg (control) and 1.0 mg/kg (highest dose). The percentage of time spent in locomotion varied significantly among the treatment conditions ($X^2r = 7.15$, df=2, $p<0.05$). Participants given the control spent, on average, five times more time in locomotor activities than they did following ritanserin administration. The finches also spent significantly more time performing ingestion behaviors when in the control condition than in either drug condition ($X^2r = 7.55$, df=2, $p<0.05$). A pattern was seen among the treatment conditions in the percentage of time spent inactive ($X^2r = 4.94$, df=2, $p=0.09$). A similar trend was observed in the time spent in nesting behaviors ($X^2r = 5.33$, df=2, $p=0.07$). Nearly twice the amount of time was spent nesting when participants were given the control.

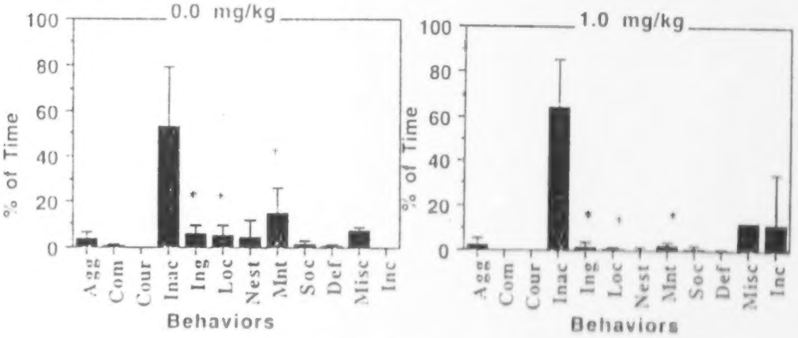

Figure 2. Mean percentage of time spent in each of the 12 behavioral categories (aggression, communication, courtship, inactivity, ingestion, locomotion, nesting, maintenance, social preening, defense, miscellaneous behaviors, and incubation) as a function of ritanserin dose (0.0 mg/kg (control) and 1.0 mg/kg (highest dose)).

The average rate of maintenance behaviors varied significantly among the conditions ($X^2r = 9.56$, df=2, $p<0.05$) with significantly fewer bouts of maintenance occurring following ritanserin administration. In addition, the percentage of time finches spent in maintenance decreased significantly with increasing exposure to ritanserin (Figure 2: $X^2r = 12.48$, df=2,

BEST COPY AVAILABLE

$p<0.05$). A trend among the conditions also existed in the rates of ingestion ($X^2r = 5.27$, df=2, $p=0.07$), in that during the saline condition there were twice as many bouts of ingestion than during either ritanserin condition.

DISCUSSION

The finches engaged in more ingestion and maintenance behaviors following ritanserin administration than after methysergide injections. In addition, the participants did not display as many "miscellaneous" behaviors, such as "coughing," twitching, and crouching when injected with ritanserin. Although inactivity was significantly greater after methysergide treatment, only a slight trend in greater inactivity was seen following ritanserin administration. Correspondingly, there was no significant difference among the treatment conditions for aggressive behaviors following either antagonist. Similar to methysergide, for the majority of the behaviors observed, the effects of the two ritanserin conditions did not significantly differ from one another but were significantly different from the control condition.

Because observed behaviors after ritanserin administration resembled those behaviors after methysergide administration, the hypothesis that serotonin may be the neurotransmitter responsible for the behavioral effects in the finches is supported. There are only a few findings of decreased aggression and increased inactivity due to ritanserin administration in the existing published literature on animals. Elliott, Walsh, Close, Higgins, & Hayes (1990) found that ritanserin increased cataleptic behavior (similar to inactivity) in both rats and marmosets. Sommerfelt & Ursin (1993) note that slow wave sleep was increased following ritanserin administration in humans and rats. And a study on mice (1991) demonstrated that ritanserin inhibited isolation-induced aggressive behavior at a high but not debilitating dose (10 mg/kg, i.p.), (White, Kucharik, & Moyer).

Future studies must now determine the role of these antagonists in blocking serotonin receptors in bird species such as zebra finches. It is important to determine how the finches' neurochemical systems relate to other animal species studied in order to resolve whether these differences are due to different physiological mechanisms.

Context and Quality of Social Interaction of Children with Severe Language Delays in a Full Inclusion Preschool Program

Amy Buchanan and Krista DeZerega

Department of Human and Community Development,
University of California at Davis
Davis, CA 95616

Faculty Advisors:

Dr. Lawrence V. Harper and Staff Research Associate Karen McCluskey, M.S.

On the assumption that young children learn through interaction with others, this study focuses on the social interactions of children with mild or severe oral language delays and their peers (those who are developing normally and those with other special needs) in a full inclusion preschool. Videotapes of 16 children (4 with no more than modest language delays; 4 with severe language delays; and 8 normally developing peers matched for age and gender) were coded for this study. Subjects were previously videotaped for approximately 20 minutes each during free play for a larger ongoing study. Four tapes per child were scored episodically whenever a subject engaged in interaction with peers or with both peers and adults together. Each episode was coded for context of activity (gross motor, sedentary, themed activity, or transition), quality of interaction (positive/neutral or negative; equal or unequal in status), occurrence of adult facilitation, and the make-up of the peer group. Analyses revealed that children with severe language delays spent less time in social interactions than did their normally developing peers and their peers with lesser language delays. However, within their limited interactions, it was found that children with severe language delays spent more time in interactions involving gross motor play, and spent more time in interactions that were facilitated by adults than did their normally developing peers.

BACKGROUND

In the past decade there has been an increase in preschools mainstreaming children with disabilities, due, in part, to the Education of the Handicapped Act Amendments of 1986 (PL 99-457). This Act mandates that states provide early intervention services in the least restrictive environment to all eligible children from birth to 5 years of age (Rice, 1993; Thiele & Hamilton, 1991). Now that there is legal support for all children to participate in the same educational programs, questions have risen with respect to how the interactions among this diverse population influence individual development. Lev Vygotsky suggests that, "Education generates and leads development, which is the result of social learning through the internalization of culture and social relationships" (Gindis, 1995; Vygotsky, 1978).

Social interactions are important because they are thought to promote cognitive, social, and emotional development (Siegel, et al., 1985; Piaget, 1932; Hartup, 1976). Rice (1991) states that a child's development may be influenced by language ability, while social interactions may play a specific role in the enhancement of language development. By enhancing developmentally important social interactions, with opportunities to interact with peers who are developing normally, children with language delays may benefit from attending a full inclusion program. While some findings have shown the benefits of social interactions, other research has shown that children with language delays may be "at risk" for social isolation (Harper & McCluskey, 1996). Therefore, recent studies have focused on children with special needs, their participation in social interactions, and the resulting influence that it has on their development. Guralnick (1990) reported that

> "handicapped children form a socially separate subgroup in preschool settings. In general nonhandicapped children tend to interact far less frequently with handicapped children than they did with other nonhandicapped children ... Moreover, greater degrees of social separation are found for children with more severe disabilities" (287). "Handicapped children are perceived as being of lower social status and are treated accordingly as reflected in speech style analyses ... this latter pattern is also found when delayed children interact with other delayed children' (294)".

Further research by Guralnick has supported the notion that children with special needs may have more frequent interactions with children developing normally depending upon the relative success of their interactions. He found that children with communication disorders were more successful when interacting with their normally developing peer groups than with their peers with special needs (Guralnick et al., 1996).

Several studies suggest that children with communication disorders in a mainstreamed setting are less socially integrated because of the tendency for children with language delays to be involved in groups with both adults and peers and not in groups with their peers alone. Children with delays interacted less with their peers and more with adults than did children developing normally (Daily, 1996; Hadley & Rice, 1991, Guralnick et al. 1996). While research has shown

BEST COPY AVAILABLE

that adults are a part of such interactions, little is known of the effect of the adult's participation in the interaction or of the context of activities in which these interactions typically take place. The present study focused in more detail on the peer social interactions of children with language delays, both with and without adult involvement to examine what role adults play in the facilitation of such involvement. Additionally, this study focused on the context of the children's interactions, including their activity (gross motor, sedentary, and themed activities, or transition) and who they are interacting with (children developing normally, children with special needs, or both).While some research has examined what kind of play (i.e., solitary, parallel, and group play) children with language delays are involved in during interaction, few have examined the context of the child's play activities (Guralnick & Groom, 1987; Hadley & Rice, 1991).

This study is focused on the types of activities in which these children were engaged during interaction, who was involved in the interaction, and the quality of the interaction. This research was conducted to answer the following questions: What are the effects of speech and/or language impairment on the social interactions among preschool children? Compared to their peers, do children with severe language delays: spend more or less total time in interaction? spend more or less time in interaction while involved in an activity? spend more or less time in interaction involving adult facilitation? engage in more positive or negative interaction? engage in more interaction that is equal or unequal in status? How do these interactions affect the child's development and social relationships? Hypotheses for this study were that children with language delays would spend less time in overall interaction; less time in specific activities such as gross motor play, sedentary activities, and themed activities, and more time in transition; have more interactions involving adult facilitation; and have more interactions that are negative and unequal in nature.

METHOD

Subjects

A total of 16 preschool children attending either a morning or an afternoon preschool at the Center for Child and Family Studies (CCFS) at the University of California at Davis were selected for this study. All were a part of a longer, ongoing study being conducted at the CCFS. Subjects ranged in age from 38 months to 58 months (M = 49). Eight children with a variety of special needs including Cerebral Palsy, Autism, and Down Syndrome, were matched by sex and approximate age to 8 children who were developing normally.

For the purpose of this study, subjects were grouped based on language ability. Eight of the subjects were developing normally with no language delays. Four of the subjects with special needs had no more than modest oral language delays; while four had very severe oral language delays. The children in this last group were virtually without expressive oral language abilities. Children who were incapable of independent locomotion, regardless of their language abilities, were not included in the study as subjects.

Setting

The CCFS is a full inclusion preschool which can be described as a least restrictive environment. The preschool philosophy emphasizes and promotes cognitive, social and emotional development through exploration and autonomy. The adults in the classroom included a program director, the classroom head teacher(s), a special education teacher, and 6 to 8 advanced student teachers. With a caregiver-child ratio of 1:4, the classroom consisted of approximately 30 children developing normally and 5 children with special needs. Student teachers often worked in conjunction with the special education teachers, assisting with children with special needs. The preschool has both a morning and an afternoon program where free play is scheduled into the children's daily activity. During this time the children have access to both indoor and outdoor activities including themed areas, such as a doll house or tractor; arts and crafts areas; climbing structures for gross motor play; and quiet areas for individual reading, puzzles, and blocks.

Procedure

Four videotapes each of selected subjects were drawn from those collected as part of a larger study at the CCFS. In that study, children were filmed in 20 minute blocks of time during their free play periods using a Panasonic VHS video camera and a Realistic FM wireless microphone transmitter and receiver. Each child wore a "belt" with a pouch containing the microphone transmitter. This allowed researchers to film children from quite a distances while maintaining good quality sound on the recording. For this study, the total videotaped observation time per subject for the four observations selected ranged from 71.83 to 91.42 minutes (mean = 81.4).

Data was coded in real time and entered into a spread sheet on Excel. Episodes were scored according to time on the VCR clock counter and time was reset at the beginning of each observation. Each time there was a change in a codeable variable a new interaction was scored. Total length of each video taped observation was also recorded. Interactions were coded episodically for the following variables: context of activity, quality of interaction, adult facilitation, type of interaction, and peer(s) involved. Context of activity included Gross Motor (large body movements such as running, climbing, bicycle riding), Sedentary (reading, arts and crafts, puzzles), Themed Activity (make-believe play, with or with out objects) and Transition (movement between activity; not engaged in any activity). Quality of Interaction was coded as either Negative (interactions involving conflict and/or unpleasant, hostile or rejecting behavior) or Positive/Neutral (all instances where the interaction was not negative; includes smiling, laughing, and pleasant or helpful behaviors) and Unequal (interactions where the subject or peer treats another in a condescending or developmentally unequal manner, perhaps with the use of "motherese" type language) or Equal (respectfully speaking to others as though they are at the same developmental level). Adult Facilitation defines whether an interaction was Facilitated (when a caregiver is present and is involved in the subject's interaction, acting as a communication center or mediator) or Non facilitated (an interaction that is not dependent on the absence or presence of the caregiver). Type of Interaction was coded to examine who was involved in the interaction. This could be either Interaction Peer (peer to peer) or Interaction Both (both children and adults). The variable of Peer(s) Involved codes for who the subject is interacting with: Developing Normally (all children who are developing normally), Special Needs (all subjects with developmental disabilities, including other children at the center who are motorically impaired but who are not subjects for our study) or Mixed Group (both children developing normally and those with special needs).

Two observers evaluated 12% (N=8) of the videotapes for final training and refinement of coding before assessing interobserver agreement. Confusion matrices were made for each of the following groups of variables: context of activity, quality of interaction and adult facilitation, and type of interaction and peer(s) involved. Interobserver agreement was then assessed on 6% (N=4) of the videotapes and Cohen's Kappa was calculated to measure the agreement between observers, correcting for chance. Kappa was .74 for context of activity, .80 for quality of interaction/adult facilitation, and .86 for type of interaction/peer(s) involved.

The data were aggregated across observations for each subject. Percent of total observation time in interaction, as well as percent of interaction time for each of the variables was computed. The three groups were then compared for significant results using a Mann-Whitney U sum of ranks test. We compared the three groups for percent of total observation time spent in interaction and percent of actual interaction time spent in each variable.

RESULTS

The interactions of children developing normally were compared to those of their peers who had moderate and severe language delays, likewise, all other crosswise comparisons between groups were made. As shown in figure 1, normal children and those with modest language delays spent significantly more time in interaction than did children with severe language delays (p = .0243) and (p = .0285) respectively. There were no differences in overall interaction time between normal children and those with moderate delays.

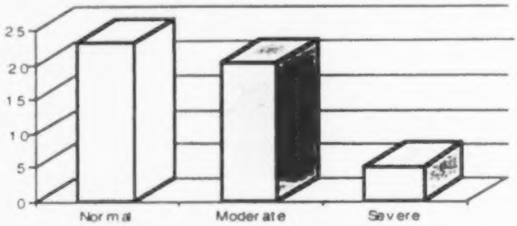

Figure 1. Percent of Total Observation Time Spent In Interaction

Two statistically significant differences were found between groups in the context of interactions. Of their actual time spent in interaction, children with severe language delays engaged in proportionally more gross motor play compared to their normally developing peers (p = .0081). Additionally, children with moderate language delays spent less time in transition, not involved in any specific or organized activity (p = .0035) compared to their normally developing peers. There were no significant differences found between groups in sedentary or themed activity (see Figure 2).

BEST COPY AVAILABLE

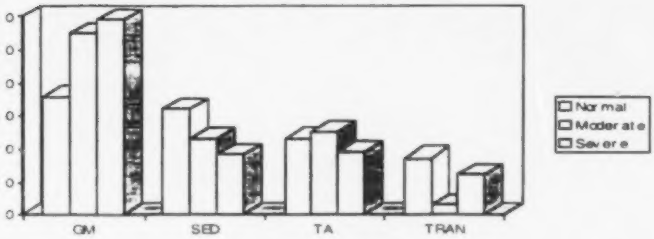

Figure 2. Percent of Interaction Time for Context of Activity

Although there were no group differences in the quality of interactions or the make-up of the peer group, there was an influence of adult facilitation on the relative interaction times of the normal children and those with severe language delays. Significant differences revealed that children with severe language delays had relatively more interactions when an adult facilitated the interaction (p = .0243) and relatively fewer interactions when there was no adult facilitation (p = .0243) when compared to their normal peers.

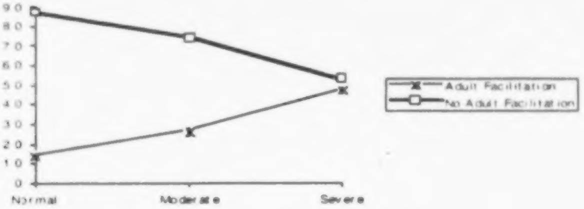

Figure 3. Percent of Interaction Time Involving Adult Facilitation

DISCUSSION

The results of this study indicate that children with severe language delays spent less time in peer interaction than their peers with moderate language delays and those developing normally. This finding supports the results of Hadley & Rice (1991), who found that children with limited communication skills were involved in proportionately fewer peer interactions than their peers developing normally. It is important to note that Hadley & Rice (1991) were looking at the number of interactions while the present study examined the percent of time in interaction for children with severe language delays. Harper & McCluskey (1996) found that, while the number of episodes involving interaction did not differ between groups, there was a significant difference in the percent of time that children with language delays engaged in social interaction when compared to children developing normally. Both studies support the idea that differences in language ability contribute to a child's overall participation in social interaction.

Of their actual time spent in interaction, children with severe language delays spent more time in gross motor activity than did their peers developing normally. More of the interactions of children with severe language delays were during gross motor play (59%) compared to their time spent interacting in other activities: sedentary (18%), themed activity (19%) and transition (12%). This difference may be because gross motor activities generally include more body language and physical contact than verbal communication, while activities such as sedentary play and themed activities involve greater use of verbal communication. Rice & Hadley (1991) suggest that children with severe language delays had a lower proportion of episodes interacting during activities such as dramatic play because they involve greater conversational demands and more advanced communication skills. Therefore children with severe language delays may benefit if more activities were less dependent on oral language and more supportive of other modes of communication. The results of this study may suggest that children with language delays spend less time in interaction because they do not have the means to sustain exchanges in verbal communication.

Compared to their peers developing normally, children with severe language delays had a greater percent of interaction time involving adult facilitation. This overall pattern of increasing involvement of adult facilitation with an increase in language severity could imply that these children with increasing language delays are increasingly dependent upon the support of caregivers as moderators and facilitators of their social interactions. There were no differences in the quality of the interactions between the three groups, thus there must be something else that is contributing to the minimal interactions of children with severe language delays. The findings show that the interactions of children in a full inclusion setting may be a function of their environment. Children with special needs, specifically those with language delays, are in need of activities that promote interaction through nonverbal means, allowing these children to have more interaction with their peers. Children with language delays may be in need of adults who will facilitate their involvement in social interactions with their peers.

This study is limited due to a small sample size of 16 children. The subjects were nonrepresentative of the general population being students at a University preschool where the abundance of caregivers and ethnic diversity of the preschool class may have had a substantial influence on their interactions. Although none of the subjects had major motoric impairments, they may have had other disability factors (Downs Syndrome, Cerebral Palsy, Autism) that contributed to their limited time in interaction. In addition, due to constraints in time, a sequential analysis of the data was not made, nor was there an examination of the data across variables. The data shows how much time each child spent interacting in gross motor activity, but does not show how much of that time involved adult facilitation.

Future research is needed to examine the effect of adult intervention and influence on positive interactions among children with and without language delays, and to examine how the environmental features of a full inclusion preschool might be modified to promote success in social interaction. Also, more information is needed about the mode of communication used in interactions, with implications for how it affects a child's overall time in interaction.

ACKNOWLEDGMENTS

Thank you to Dr. Lawrence V. Harper, and Karen McCluskey, M.S., our sponsoring faculty for their support. Special thanks to Leanne Friedman, William Town, and the Department of Human and Community Development for their contributions to our research.

Characteristics Associated with Premature Drop Out in Client-Centered Play Therapy

Valerie A. Campbell
David B. Baker

University of North Texas
Denton, TX 76203
(817) 565-2671

Faculty Advisors:

Sue Bratton and Jennifer Cleveland

According to previous research, Client-Centered Play Therapy (CCPT) is effective with a variety of childhood problems. CCPT allows children to work with their problems at their own pace. Although CCPT has popular support, it has also been shown that a large portion of children in CCPT do not complete their treatment. In an effort to examine these issues in greater detail, this study examines and compares the characteristics of clients who do and do not complete CCPT. Subjects of this study consisted of 48 girls and boys ages 4-14 who received CCPT at a university-based child and family outpatient counseling clinic. Factors important in differentiating successful from non-successful completers included: mother's age, education, child gender, and living arrangements.

BACKGROUND

Few databased research studies have been conducted on the characteristics of the effectiveness of Client-Centered Play Therapy (CCPT), in comparison to other child psychotherapies. CCPT assumes children can solve their own problems and are capable of re-creating their world and their relationship to it in play (Landreth, 1991). Ginsberg (1993) defines the objective of CCPT as:

> Essentially, the objective in Client-Centered Play Therapy is to provide a context in which a child's own resources are utilized to foster change and growth. Under these conditions, attention needs to be directed toward the context of play sessions, materials used, limits including time, therapist's behavior, and the interaction of these components to provide opportunity for the child to be free to express those feelings and to take more responsibility for them (p. 124).

Studies have shown CCPT to be effective in the following areas: (a) decrease and alleviation of aggressive acting-out (Barlow, Strother, & Landreth, 1985; Willock, 1983), (b) improved emotional adjustment of children of divorced parents and of abused and neglected children (Mendell, Mann & McDermott, 1983), (c) reduction of stress and anxiety in hospitalized children (Golden, 1983), (d) increased and corrected academic and speech performance (Axline, 1947, 1949; Guerney, 1983, Pumfrey & Elliot, 1970), (e) decreased emotional and intellectual problems of the mentally retarded (Leland, 1983; Leland & Smith, 1962; Pothier, 1967), (f) better social and emotional adjustment and improved self-esteem (Axline, 1948, 1964; Bleck & Bleck, 1982; Crow, 1989; King & Ekstein, 1967; Pothier, 1967; Ude-Pestel, 1977), (g) amelioration of elective mutism and stuttering (Barlow, Strother & Landreth, 1986; Wakaba, 1983), and (h) relieving psychosomatic difficulties such as asthma, ulcerative colitus and allergies (Dudek, 1967).

Given that CCPT, along with other child psychotherapies have proven their effectiveness, it is surprising so many leave treatment prematurely. It is not uncommon in a variety of mental health settings for 50% of clients to leave treatment without prior knowledge and agreement of their therapists (Pekarik, 1983; Phillips, 1985). Since it is desirable to have clients stay for the full duration of treatment, it is important to investigate the characteristics of those who terminate prematurely.

Kazdin and Mazurick (1994) examined early and late terminaters in child psychotherapies in general. The results of the study indicated no significant differences when examining therapists, treatment conditions, and age and sex of the child as variables. Discriminant function analyses combining early and late terminaters and comparing them to the completers indicated that mother's age, single-parent family, child history of anti-social behavior, child contact with anti-social peers, receipt of public assistance, number of conduct disorder symptoms, and child IQ were all strong contributing factors of premature termination. The terminators tended to be younger mothers, single parents, nonbiological parents, more likely to be from a minority group, and those who had more severe child impairment in relation to conduct, academic disjunction, and social behavior.

Kazdin, Mazurick, & Siegal (1994) conducted a study of various child psychotherapies to see whether individuals who drop out of therapy are more severely impaired to begin with (pretreatment) or whether they differ on subject and demographic characteristics that contribute to dropout. Results revealed terminators had greater socioeconomic disadvantage, more stressful living conditions (e.g., single parents, more perceived stress, more life events), and more severe and chronic child dysfunction. The study also found that those who completed treatment made larger gains than their matched counterparts who dropped out (when comparing progress in pretreatment problem areas). While these studies provide insights into general issues of termination in child psychotherapy there are no studies that examine the issue in children receiving CCPT. The focus of this study is to examine specific variables of those clients who do not complete therapy and to compare them to those who do complete.

METHOD

Participants

Forty-five families served as participants in this study. The sample was drawn from closed treatment files covering seven consecutive years at a university-based child and family outpatient-counseling clinic. Description of subject selection and characteristics are included in the procedure section.

Instruments

All clients in the study completed the following measures as part of the initial procedure. The Parenting Stress Index scores (PSI; Abidin, 1986), Child Behavior Checklist, (CBCL; Achenbach, 1991) and demographic information.

Procedure

To be included in the study, parents must have completed an intake interview, completed the measures describe above and brought their child to at least two sessions of client-centered play therapy. Graduate students conducted therapy with training in CCPT at a university-based child and family-counseling clinic.

The demographic questionnaire assessed the age, gender, ethnicity, and living arrangements of the child as well as parental age and education, and reason for referral.

In addition to the information gathered as part of the intake information, therapist's experience and gender were coded along with termination status. Completion and non-completion was determined by a review of the client's files. The non-completion group included those who: (a) never returned, (b) had a schedule conflict and never returned, (c) insisted on termination, or (d) were assigned a new therapist and never returned. The completer group included those were judged to have successfully completed treatment. This decision was based on a mutual agreement between the therapist and client that treatment was successfully completed.

The final sample included 45 children and their parents. While both parents were encouraged to attend the intake interview and complete the measures, mothers were the primary respondents and the subsequent data analysis using the CBCL and PSI were based on maternal reports. Of the 45 children who received CCPT, 28 were non-completers(NC)and 17 were completers(C). Of the non-completers, 61% (n=17) were male and 39% (n=11) were female. In the C group, 88% (n=15) were male with 12% (n=2)being female. In the NC group 21% (n=6) lived with both biological parents, 14% (n=4) lived in two parent households with remarried parents, adoptive parents, or relatives, and 65% (n=18) lived in single parent families. Of the C group 47 % (n=8) lived with both biological parents, 24% (n=4) lived with stepparents, and 29% (n=5) lived in single parent families. The majority of children in both the NC and C groups were Caucasian (94% and 100% respectively). Reasons for referral were categorized into three broad groups, Internalizing Problems (including emotional and self-esteem problems) , Externalizing Problems (including behavior problems, ADHD) and Social problems (including social and family problems. Percentages for these categories for the C group was 47 % (n=8) Internalizing problems, 47% (n=8) Externalizing problems, and 6% (n=1) Social problems. For the NC group 36% (n=10) presented with Internalizing . 53% (n=15) with Externalizing , and 11% (n=3) with

BEST COPY AVAILABLE

Social problems. Additional characteristics of the sample are presented in Table 1.

RESULTS

The categorical variables, child gender and living arrangements were examined using Chi-Square tests. A 2 x 2 chi-square analysis indicated a significant relationship between group status and gender ($x2 = 3.90$, $p < .05$). There were significantly more boys in the completer group than in the non-completer group. To analyze living arrangements, categories were collapsed to increase cell sizes resulting in two categories, living in a two-parent household or living in a single parent household. A 2 X 2 Chi-Square analysis was significant ($X2 = 5.148$, $p < .03$) indicating that children in the NC group were more likely to live in a single parent family. Next, a series of univariate analyses of variance (ANOVA's) were performed on the demographic variables of child age, maternal age and education, and number of sessions attended. Results are presented in Table 1. There were significant differences between the groups for mother's age ($F = 4.38$, $p<.05$) and mother's education ($F = 4.66$, $P < .05$). Mother's age and mother's education (in years) were both lower in the non-completer groups. A second series of ANOVA's examining parental stress and child behavior failed to reveal significant differences between groups. Results are presented in Table 2. Finally, the therapist variables of level of experience and gender were examined. Therapist experience was rated as either beginning (had taken a course in CCPT and completed a supervised practicum) or advanced (had completed advanced CCPT coursework and practicum). Using these criteria 82% (n=14) of the therapists in the completers group were beginning and 18% (n=3) were advanced. For the noncompleter group 64% (n=18) were beginning therapists with 36% (n=10) being advanced. Results of a 2 X 2 Chi-Square analysis were not significant. A final Chi-Square analysis showed a significant relationship between therapist gender and completion status ($X2 = 4.71$, $p < .03$). There were significantly more male therapists in the Completion group. Eighty two percent (n=14) of the therapists in the C group were male and 18% (n=3) female compared to 50% male (n=14) and 50 % female (n=14) in the NC group.

Table 1: Sample Characteristics and ANOVA's

Variable	Completion Group (N = 17) M	SD	Non-Completion Group (N = 28) M	SD	F
Child Age	8.53	2.70	7.30	2.60	2.80
Maternal Age	38.40	5.02	33.00	9.40	4.38*
Maternal Education (in years)	15.00	2.60	12.90	2.90	4.66*
Number of Sessions Attended	13.53	6.80	11.03	8.25	0.42

*$p < .05$

Table 2: Parenting Stress and Child Behavior ANOVA's

Variable	Completion Group (N = 17) M	SD	Non-Completion Group (N = 28) M	SD	F
Parenting Stress Index					
Child Domain	125.25	22.30	125.20	22.30	0.00
Parent Domain	127.10	26.10	135.20	27.00	0.94
Child Behavior Checklist					
Internalizing	58.00	10.15	62.30	14.40	1.12
Externalizing	58.50	12.51	63.03	16.10	0.90

DISCUSSION

The findings of this study were consistent with the findings of Kazdin and Mazurick (1994) in regards to the non-completer group consisting children with younger mothers living in single parent households. In addition, the current study found that the level of maternal education was lower for mothers whose children did not complete CCPT. These results were independent of number of sessions attended or age of the child. Although analyses did not reveal significant results there tended to be certain trends in the data that support previous studies. There was a tendency for the non-completers to be referred more often than the completers for externalizing behavior problems and social problems. Similarly, parent reports of child behavioral problems tended to be higher in the non-completer group. There was some indication that parenting stress due to parental characteristics was higher in parents in the non-completion group. Compared to the sample in the Kazdin and Mazurick study (1994) the sample in this study may be less impaired in terms of environmental stressors and child behavior problems. However, taken together the data would suggest that the stress and hardship presented by being a young single parent with less educational experience and a child with externalizing behavior problems makes compliance with child psychotherapy more difficult.

Unlike Kazdin and Mazurick (1994) there were significant effects related to gender. In the current study, the completion group was composed primarily of boys. Similarly, the therapists of children in this group were also predominantly male. This suggests that matching of child and therapist gender in CCPT may enhance completion of treatment.

There are several limitations that restrict generalizations that can be made about child psychotherapy in general; and CCPT in particular. The sample in the study was homogeneous in terms of ethnicity being exclusively Caucasian. In addition services were provided in the context of a university based clinic and as such may have attracted families who were familiar and comfortable with the university environment. The small sample size also warrants caution as in the case of the interesting findings in regard to therapist and child gender. Replications using a larger sample size with more diverse demographic characteristics would increase external validity and generalizability.

Overall, the findings would suggest that there are more similarities than differences between those who fail to complete CCPT and terminators from child psychotherapy in general. The results of this study as well as those of others would strongly suggest that factors related to completion or termination of child psychotherapy are more related to demographic and life situation factors than to the type of treatment approach utilized. It seems rather evident that those most at risk for premature termination are young single mothers who may have less educational opportunity and training and who have children with externalizing behavior problems. Attempts to address the issues of stress in the lives of these mothers and ways to combat it may help facilitate successful participation in child psychotherapy.

Helping Behavior Rates and Demographics: A Comparative Analysis

Nancy Steblay

Steblay's 1987 meta-analysis examined the relationship between population size and bystander helping behavior, finding only a small negative correlation ($r = -.10$). In this study I hypothesized that two demographic variables, population density and racial heterogeneity, would have a stronger link to helping rates. The U.S. Department of Commerce and Bureau of the Census provided demographic information for the 24 cities included in Steblay's analysis. Steblay's review provided the bystander helping behavior data. In support of the hypothesis, a negative correlation was found between population density and helping behavior, $r = -.48$, $p = .009$, and between helping behavior and racial heterogeneity $r = -.68$, $p = .000$. Discussion will examine theoretical reasons for these relationships.

INTRODUCTION

The rural-urban hypothesis suggests that rural people are more helpful to strangers in need of help than are urban people. Many studies have tested this phenomenon, with mixed results. Steblay (1987) went one step closer to understanding the rural-urban phenomenon by synthesizing data that tested this hypothesis. In a meta-analysis which included 35 studies, the relationship between helping rates and population size was not as strong as anticipated, $r = -.10$. This small relationship suggests that other variables, besides population size, account for differential helping behavior rates in rural versus urban areas.

The logical next step is to explore other variables that could assist in the explanation of helping behavior rates in rural settings versus urban settings. The two demographic variables that will be considered in this study are population density and the racial diversity of a population.

Population Density

A study done by Levine, Martinez, Brase, and Sorenson (1994) examined helping rates in 36 cities. They found that the correlation coefficient reflecting the relationship between helping rates and population density was higher ($r = -.44$, $p < .001$) than the coefficient which resulted from correlating helping behavior and population size ($r = .04$). This supports Milgram's overload theory of urban living (1970). He suggests that in highly populated areas, the responsibility to help may be transferred to other onlookers, thus the low bystander helping behavior in densely populated areas.

Racial Diversity

This variable has not been considered as a specific means to explain helping behavior in urban versus non-urban areas. However, theorists have suggested that heterogeneity is an important issue when understanding human interaction and population (Wirth, 1938; Fischer, 1975). Studies have compared helping behavior across cultures (Yousif & Korea 1995; Hedge & Yousif, 1992), but for the purpose of this study, the diversity within a city is important.

Fischer (1975) theorized that a large population supports subcultures. He suggested that the more populated a geographical area is, the greater the potential cohesion of constituent subgroups. Applying this rationale, it is reasonable to predict that, while bystander helping behavior may be greater within subcultures, it will be less across subcultures.

Because cities contain many subcultures, racial heterogeneity could create fear or apprehension toward helping. This notion is supported by a study done by Heald-Moore (1995), in which she found that "whites are more fearful of encountering black than white strangers and blacks appear to be slightly more fearful of encountering white than black strangers" (271). According to Milgram's (1975) overload theory, "the city dweller can reduce excessive demands and screen out urban heterogeneity by responding along ethnic lines"

BEST COPY AVAILABLE

(1426). There are many elements that contribute to the urban overload theory; among them are the two variables considered in this study, population density and racial diversity. Therefore, the more racially heterogeneous a population, the less likely a stranger, of any race or ethnicity, will receive help.

The intention of this study is to add to the understanding of Steblay's (1987) hypothesis which suggested that people of a rural area were more helpful to strangers than those of the city. Where the meta-analysis used population size as a variable gaining insignificant results, bystander helping behavior is correlated with population density and racial diversity. The more densely populated an area is, and the higher the heterogeneity of the population, the less likely a stranger will receive help.

METHOD

Participants

Demographics were sought for 19 United States cities and five United States towns out of the 35 studies which were included in the meta-analysis (Steblay, 1987). This study did not include all of the cities considered in Steblay's analysis because towns with populations less than 1,000, cities vaguely labeled, and populations located outside of the United States, were not represented in the census data.

The different kinds of helping behavior "categories rang[e] from simple requests (e.g., give time of day) to quite demanding pleas (e.g., help an injured pedestrian)" (348). All the studies included in the meta-analysis tested helping behavior as a contextual variable. This means "that the helping test took place either in a rural area or in the city" (349).

Procedure

The information used to statistically refute or accept the null hypotheses came from several sources. The studies included in Steblay's (1987) meta-analysis supplied the bystander helping behavior rates. Because most of these studies were done in the late 70's and early 80's, the population size and racial demographics were extracted from the United States Department of Commerce & Bureau's *1980 Census of the Population*. Finally, land area, which is necessary to compute population density, was found in the *1990 Census of Population and Housing Unit Counts*.

Racial heterogeneity was defined by counting the number of ethnic groups of 20 persons or more within a city or small town. The Bureau of the Census created 16 categories, all of them included in the count. Between three to 16 categories were found in each city.

RESULTS

A one-tailed bivariate correlation coefficient was calculated to test each of the two hypotheses. The first hypothesis stated that helping rates would drop as a population increased in density. Twenty-eight bystander helping behavior rates gathered from different parts of the U.S., including 19 cities and five small towns, were correlated with population density, yielding a negative relationship of $r = -.48$, $p = .009$, (CI 95%: -.71 to -.21).

The second hypothesis suggested that the more racially heterogeneous a population was, the less likely bystander helping behavior would occur. Correlating helping behavior rates with the number of ethnic groups within a population resulted in $r = -.68$, $p = .000$, (CI 95%: -.82 to -.46).

If bystander helping behavior is low in a racially heterogeneous society, it should be high within a homogeneous population. Because the small town populations considered in this study are predominately white, the Caucasian demographic represented homogeneity. The correlation between bystander helping behavior and the percentage of Caucasian race resulted in $r = .41$, ($p = .02$).

DISCUSSION

The results of this study show that the variables population density and racial heterogeneity have significant relationships to bystander helping behavior. The higher the population density and racial heterogeneity, which are characteristics of city life, the lower the bystander helping behavior. This helps to explain Steblay's (1987) rural-urban hypothesis in a way that is correlational not causal.

Population density

Not only do findings support the study done by Levine et al. (1994), they also relate well with Milgram's (1970) overload theory. The overload theory suggests that people in urbanized areas are likely to keep high level societal stimuli under control by creating tighter boundaries. Milgram maintains that a person has "filtering devices" which help to minimize social interactions. The desire for low social interaction may be one reason for decreased bystander helping behavior in densely populated areas.

Racial diversity

A significant negative correlation was found between racial diversity and bystander helping behavior. When considering the theoretical implications of the findings, two shortcoming must be evaluated. First, the studies included in Steblay's meta-analysis did not point out the race, ethnicity, or whatever could suggest that the helper was from a subculture which differed from the person receiving the help. Second, the studies did not indicate which part of the city or small town the bystander helping behavior was tested. Demographics of a city can change within blocks. Therefore, racial diversity is one element of the heterogeneous makeup of city life.

Fischer's (1975) theory of subcultures and Milgram's (1970) overload theory help to theoretically explain the findings, however, building a sense of community may provide better insight. That is, even if a neighborhood were racially heterogeneous, residents' knowledge of one another may create a sense of security, hence an increase of bystander helping behavior. The support for this is found in the correlation between homogeneity and bystander helping behavior.

The conceptualization of racial homogeneity comes from the fact that the small towns included in this study were dominated by a Caucasian population. The percentage of Caucasians in an area, such as city or town, were positively correlated with the bystander helping behavior. The more homogeneous a population, the more likely bystander helping behavior will occur.

Reiss (1974) may explain high bystander helping behavior in rural areas by comparing the different ways in which humans interact in the rural community and the urban populated area. He suggests that people of the small towns have higher face-to-face contact and have longer lasting, strong relationships with each other then the people who live in the city. This creates a sense of stability and security. Consequently, if an event occurs out of the norm in the subculture - a stranger in need of help - the rural citizen feels safe to extend a hand.

The strong correlations investigated in this study help to explain the rural-urban hypothesis Steblay (1987) predicted in her meta-analysis. That is, "Country people are more helpful than city people" (346). It is wondered if the urbanites can learn from the citizens of rural USA. Because a rural area has a small population size, it allows residents to become familiar with one another. By having block parties or by having a community center, neighborhoods within an urban area could gain the same sense of community as a small town. Knowledge about the general routine of the people who live within a close proximity may help a resident gain the feeling of stability, thus increasing bystander helping behavior. To strengthen the validity and the reliability of this study, bystander helping behavior should be tested within areas of a city that have made the conscious effort to create the sense of community, whether they are predominately white, black, Asian, or racially diverse.

Parents' Marital Status, Father-Daughter Intimacy and Young Adult Females' Dating Relationships

Kristen J. Clark

Raleigh, NC 27604

Faculty Advisor
Korrel Kanoy

The affective relationships of young adult females and their fathers were investigated for effects on dating relationships, dating anxiety, and interpersonal trust. Ninety-six college females completed questionnaires about father-daughter intimacy, dating satisfaction, dating anxiety, and trust. It was hypothesized that females with divorced vs. married parents, and females scoring lower on the intimacy scale, regardless of family structure, would experience less father-daughter intimacy, lower dating satisfaction and trust, and higher dating anxiety. Multivariate analysis of variance showed that females with divorced vs. married parents experienced significantly less intimacy with their fathers but similar levels of trust, anxiety, and satisfaction. Comparisons of females high and low in father-daughter intimacy showed no differences in trust, anxiety, or dating satisfaction. The relative importance of parents' marital status versus other factors relevant to divorce (e.g., intimacy, presence of a stepfather) will be discussed.

INTRODUCTION

Divorce has become a common occurrence in the lives of children today. At least two out of five children will see their parents separate while growing up (Ahrons & Rodgers, 1987). Research on the consequences of parental divorce on children has focused mainly on the adjustment of children under age 18. Less attention has been given to the long-term effects of childhood family structure on parent-child relations and interpersonal relationships in young adulthood (Cooney & Uhlenberg, 1990).

Following divorce, many children experience a decrease in the quantity and quality of contact with the noncustodial parent, usually the father (Amato & Rezac, 1994). Data from the National Survey of Children show that five years after divorce, nearly half of all children have not seen their fathers in the past year (Furstenberg, Nord, Peterson, & Zill, 1983). Children's separation from fathers continues into adulthood. Cooney and Uhlenberg (1990), with National Survey of Families and Households (NSFH) data on fathers aged 50 to 79, found that divorce reduced men's contact with adult children.

Teresa Cooney (1994) addressed the influence of recent parental divorce on contact and affective relations between 485 white young adults, ages 18-23, and their parents. Young adults from divorced families had less contact with their fathers, and daughters of divorce reported less intimacy in relation to their fathers than did their intact-family peers. Wallerstein & Kelly (1980) reported that 5 years after divorce, only 30% of children were able to build a mutually satisfying relationship with their nonresidential father.

Not only does divorce influence the parent-child relationship, but it also affects the child's interpersonal relations. A meta-analysis of 33 studies found that adults who experienced parental divorce as children, compared with those from married families, have poorer psychological adjustment and greater marital instability (Amato & Keith, 1991a). Research on adults and college students suggests that the experience of parental divorce in childhood is associated with reductions in the ability to develop and maintain supportive friendships and dating relationships (Slater & Calhoun, 1988 as cited in Black & Pedro Carroll, 1993). In a long-term follow up study in the United Kingdom, Wadsworth, Maclean, Kuh, and Rodgers (1990) found that both male and female college students of divorced families had less trust in a future spouse and greater dissatisfaction with the frequency of their dating relationships compared with children of nondivorced families. Those whose parents had divorced were less optimistic about the success of their own future marriages.

This finding supports research by Wallerstein (1987) who found that 16-18-year-old children of divorce, particularly young women, mentioned a sense of vulnerability and a fear of being hurt in romantic relationships. Although the participants intended to marry and believed in romantic love, two-thirds of Wallerstein's respondents were apprehensive about the possible

BEST COPY AVAILABLE

breakup of their own future marriages. Wallerstein and Blakeslee (1989) described a related phenomenon known as the "sleeper effect," where divorce has long-term negative effects on children not expected on the basis of their earlier adjustment. They wrote, "We saw many young women with acute delayed depression that is certainly a sleeper effect of divorce...A significant number of young women are living-with an intolerable level of anxiety about betrayal" (p.62).

Black & Pedro-Carroll (1993) studied the long-term effects of parental divorce, interparental conflict, and parent-child relationships on interpersonal and generalized trust. The results showed that the effects of family disruption on psychological well-being were indirect, that is, mediated by the quality of parent-child relationships. For women, parental divorce was also associated with less emotional security with their fathers. In addition, Booth, Brinkerhoff, & White (1984) found that while there were no significant differences between children of divorced and intact families, those suffering a decline in parent-child relationships as a result of divorce reported lower satisfaction with heterosexual relationships. Another possible indirect effect involves the quality of the relationship with a stepfather. Wallerstein & Kelly (1980) found that after divorce many children turned to their stepfathers and away from their biological fathers. If the children found a warm response, they came to love and admire their stepfathers and consciously choose them as role models over their biological fathers.

The present study further explored the effects divorce has on heterosexual dating relationships of young adult females. Possible differences between young adult women of divorced versus intact families were studied, as well as differences between groups higher in father-daughter intimacy and lower in father-daughter intimacy. Females with divorced versus married parents were expected to experience less father-daughter intimacy, lower dating satisfaction and trust, and higher dating anxiety. Based on the previous literature's findings that intimacy is a possible mediating factor, females scoring lower on the intimacy scale, regardless of family structure, were also hypothesized to experience less dating satisfaction, less trust and more anxiety. Due to the potential mediating effects of a step-father, an additional question was explored to determine whether differences exist between young adult women with married parents versus divorced with a stepfather in father-daughter intimacy, satisfaction, trust, or anxiety.

METHOD

Participants

The sample included 96 female college students from two small, private, women's colleges in the southeast: 66 with married parents, 25 with divorced parents, 4 with widowed parents, and 1 with parents who had never married. Scores from five participants who had never engaged in a serious dating relationship were excluded from the analysis, resulting in a sample size of 91. The participants were 95% white, middle class individuals between the ages of 18-22. Sixteen of the 25 participants with divorced parents had a stepfather. The average age at which children's parents divorced was 6.04.

Materials

The participants completed the following instruments: the Dyadic Trust Scale (Larzelere & Huston, 1980), the Heterosocial Assessment Inventory for Women (Kolko, 1985), the Adult Child-Parent Intimacy Scale (Walker & Thompson, 1983), and a questionnaire adapted from Booth et al., (1984) to assess the quality of dating relationships.

The Dyadic Trust Scale (Larzelere & Huston, 1980) contains eight items that measure the extent to which one trusts a partner. The authors report that the item-total correlations are high, ranging from .72 to .89.

The Heterosocial Assessment Inventory for Women (Kolko, 1985) consists of brief descriptions of 12 situations representing three areas of heterosocial behavior: "finding dates, making conversation, and initiating physical or sexual activity" (Kolko, 1985, p.52). The situations all focus on men. For this study, only an anxiety subscale score was examined. The split-half correlation for anxiety was .77 while test-retest reliability was .81.

Parent-child intimacy was assessed with a 17-item scale of adult child-parent intimacy adapted from Walker and Thompson (1983). The items assessed feelings that exist between the respondents and each of their parents. For this study, participants were asked to think about their feelings toward their fathers only. High scores would indicate greater father-daughter intimacy. A questionnaire was adapted from Booth et al. (1984), to assess the quality of relations for those in a serious dating relationship. Participants also answered questions that determined their serious dating relationship status. Scores from the five participants who were not currently involved in a serious dating relationship or had never seriously dated another person were not included in the analyses. If the participant was not currently in a serious dating relationship, she was asked to think about her most recent serious relationship when completing the surveys.

The author devised eight demographic items which included age, year in school, number of siblings, parental education, and parental marital status. The participants with divorced parents also answered three additional questions that included which biological parent they had lived with the most, what age they were when their parents had divorced, and the average number of weeks per year they visited with the noncustodial parent.

Procedure

At the beginning of the session, the experimenter distributed packets of surveys to the participants with the instructions to complete the surveys in the order in which they appeared. Each packet included the four surveys along with a demographic questionnaire. The adult child-parent intimacy scale was at the bottom of each packet to insure that it did not sensitize those whose parents had been divorced and cause them to respond in a socially desirable way. Survey completion occurred in one session and lasted approximately thirty minutes. The participants in both the intact and the divorced groups completed the same surveys. However, those with divorced parents were also asked to complete the parent-intimacy scale thinking about their stepfathers, if applicable. The participants' scores on the parent-intimacy scale categorized them in either the lower-intimacy or higher-intimacy groups.

RESULTS

Multivariate analysis of variance (MANOVA) showed that females with divorced versus married parents experienced less intimacy with their fathers, $F(1,83) = 20.89$, $p < .01$. Scores from the 5 participants with widowed or never married parents were not included in this analysis. No significant differences in interpersonal trust, dating anxiety, and dating satisfaction, based on marital status of the parents, were found.

A second MANOVA was conducted to compare levels of father-daughter intimacy in young women from divorced families with stepfathers and females from married families. Females from divorced families with stepfathers versus those from married families experienced less intimacy with their stepfathers, $F(1,74) = 5.77$, $p < .01$. Those with married parents scored highest on father-daughter intimacy, dating satisfaction, and trust, compared with those from divorced and divorced with a stepfather. However, young women with stepfathers had lower mean scores for dating anxiety than those with married parents. Mean scores by marital status (married, divorced, and divorced with a stepfather) are shown for father-daughter intimacy, dating satisfaction, interpersonal trust, and dating anxiety (see Table 1). As is often the case with divorce, the amount of time participants spent with their fathers declined with age. Between the ages of 0-4, participants visited their noncustodial father for an average of 18.00 weeks a year, while this figure dropped to 8.05 weeks a year between the ages of 15-18.

A third MANOVA was run for intimacy using a median split procedure to categorize participants into lower and higher intimacy groups, regardless of family structure. On a parent-child intimacy scale from 17-119, those with scores 89 and below comprised the lower intimacy group while those with scores from 90-119 were in the higher intimacy group. Comparisons of females higher and lower in father-daughter intimacy showed no differences in trust, anxiety, or dating satisfaction.

Table 1: Means and Standard Deviations by Marital Status for Father-Daughter Intimacy, Dating Satisfaction, Interpersonal Trust, and Dating Anxiety

	Married			Divorced			Divorced with Stepfather		
	M	SD	n	M	SD	n	M	SD	n
Father-daughter intimacy	104.39	21.31	66	76.88	35.93	25	86.63	31.57	16
Dating Satisfaction	16.80	3.05	66	17.50	2.95	25	16.93	2.89	16
Interpersonal trust	41.94	10.10	66	44.38	8.00	25	43.00	8.68	16
Dating anxiety	68.44	14.35	66	65.28	13.21	25	60.50	10.62	16

DISCUSSION

The current study examined the effects of parental divorce on father-daughter intimacy, dating satisfaction, interpersonal trust, and dating anxiety as reported by young adult offspring, ages 18-22. Although differences were not found between females with divorced versus married parents in satisfaction, trust, or anxiety, there were differences in father-daughter intimacy. There were also differences in father-daughter intimacy and dating anxiety between participants with stepfathers and those with married parents.

The differences in father-daughter intimacy support findings in similar studies. Cooney's (1994) study of adult children of recent parental divorce found that the young adults with recently divorced parents reported less intimate and more distant relations with their fathers than did their peers from married families. The former also noted significantly less contact with their fathers over the years. The current study also found a decline in contact with the father over time since divorce, which has obvious implications for father-daughter intimacy as well as other key variables.

The current study did not find differences in the dating relationships of females with divorced versus married parents despite the prevalence of previous research which shows that females of divorced families experience increased conflict in intimate relationships (Aro & Palosaari, 1992). One reason significant differences were not found in this study could be that young women may have recovered from the divorce sufficiently to show few negative effects other than in their intimate relationship with their noncustodial father.

A recent 10-year study (Dunlop & Burns, 1995) examined 80 young men and women who were adolescents when their parents divorced for a "sleeper effect." The "sleeper effect," first reported by Wallerstein and Blakeslee (1989) refers to the phenomenon whereby young people, especially young women, found to be coping well initially experience a significant reversal in adjustment in early adulthood. In their study, Dunlop and Burns found that, after 10 years, the adjustment of young women from divorced families had not declined in comparison to women from intact families. Specifically, no significant differences by family group were found for intimacy, relationship wariness, or relationship satisfaction 10 years after the divorce. Wallerstein & Kelly (1980) found that as children of divorce matured emotionally and intellectually, their understanding of the divorce was likely to change. In this way, their intellectual and emotional efforts to cope with the divorce were reorganized at each developmental stage and extended throughout the growing-up years. This explanation might be relevant to the current study as the average age at which participants experienced the divorce of their parents was 6. Since the divorce occurred relatively early in the lives of the young women, they might have already recovered from any effects the divorce might have had.

Even when long-term effects are found, they tend to be weak. After conducting a meta-analysis on studies dealing with the long-term consequences of parental divorce on adult well-being, Amato and Keith (1991) reported that while parental divorce has broad negative consequences for quality of life in adulthood, the effect sizes in this literature are generally weak. In addition to the weak long-term effects in the divorce literature, a second explanation for the similarities between young women with divorced and married parents may be the mediating effects of the quality of family relationships. Dunlop (1991) suggested that the degree of family conflict and the presence of a highly caring but nonoverprotective relationship - rather than the divorced or married family structure - were the most important predictors of adolescent adjustment. In the present study, 64% of the participants with divorced parents had a step-father and most reported a fairly high level of intimacy with him. Those with a stepfather scored similarly to those with married parents on interpersonal trust and dating satisfaction and also reported lower amounts of dating anxiety. Wallerstein & Kelly (1980) found that children of divorce turned to their stepfathers as models instead of their biological fathers. These children moved ahead in their development and in school, and were benefited by the divorce, which not only separated them from a psychologically destructive relationship, but also brought them an opportunity for an experience within a happy family. Also, it's possible that after seeing their mothers resolve an unsatisfactory marriage and move on to form a new relationship, the young women with stepfathers felt less anxious about their own dating relationships.

One of Wallerstein & Kelly's (1980) most important findings is the significance of the relationship at the present in determining outcome at that time. The parent-child relationships of previous years appeared not to be sufficient to maintain good functioning at the present. Because of the discontinuity in many parent-child relationships following divorce, the importance of the present relationship is especially great. Given that the overall mean score for

763

intimacy among participants with divorced and married parents in the current study was above average, this might explain the lack of significant differences in interpersonal trust and dating satisfaction between participants with divorced and married parents. If most of the participants in this study have fairly high levels of intimacy with their fathers at the present time, they might not be affected negatively in these areas.

Future research should be conducted using methodologies that rely less on self-report data which is always subject to social desirability. In addition, future research might focus on whether the effects of divorce in the life of the individual diminish over time as well. Children of divorce might be better adjusted as young adults if the divorce occurred when they were younger. As Wallerstein & Kelly (1980) discovered in their longitudinal study, it might also be that all of these different components are intricately connected. Although the various factors might seem to be functioning independently, they might be intertwined in ways that are yet to be seen. In their study, some of the components affecting the outcome of children's response to divorce included: the extent to which the child did not feel rejected in relationship with the noncustodial parent, the extent to which this relationship has continued on a regular basis, the availability to the child of a supportive human network, the extent to which the parents had been able to resolve and put aside their conflicts, and the sex and age of the child. Combining factors such as current age, recency of the divorce, mediating effects of important family relationships, and experience with their own dating relationships may reveal more about the intricate process of adjustment to parental divorce for young adult women.

Investigating Physiological Responses to Sexual Harassment

Shaunta K. Clark, Carina De Fazio, Jamar D. Barnes, Foye A. Smith

Department of Psychology
Morehouse College
830 Westview Dr. S.W.
Atlanta, Georgia 30314

Faculty Advisor:

Vernessa R. Clark

The purpose of the present study was to examine the effects of ethnic group affiliation and race of victim on physiological responses to sexual harassment in female college students. It was hypothesized that there would be no differences in the physiological responses to sexual harassment between African-American and Caucasian females. It was also hypothesized that there would be greater cardiovascular reactivity when the participants and the victim of the harassment are of the same race. Twenty students from a predominantly African-American female college and twenty students from a predominantly white female college participated in this study. The participants watched a videotape of two scenes showing females being sexually harassed by male co-workers. Measurements of heart rate and blood pressure were taken as the participants watched the videotape. T-test analyses revealed that African-American females had higher systolic blood pressure during both scenes. No significant differences were found for heart rate or diastolic blood pressure.

INTRODUCTION

Sexual harassment is known to induce stress. It is prominent in both the workplace and academia; however people have different ideas about its definition (Jaschik & Fretz, 1991). For example, Dziech and Weiner (1984) stated that sexual harassment is a broad range of behaviors that may occur singly or repeatedly. Sandler (1990) stated that the definition of sexual harassment must include a wide range of behaviors that occur at inappropriate times. Walker, Erickson and Woolsey (1985) stated that the definition must include an interaction between the person with unequal power and the person with lesser power whereas the person with lesser power is the victim.

The research on the physiological effects of sexual harassment is virtually non-existent, however, there is a small database of studies investigating the relationship between race and sexual harassment. On one hand there is much research to suggest differences in the incidence of sexual harassment based on race. For example, Gruber and Bjorn (1982) found that African-American female auto workers were more likely to be harassed on the job than their white counterparts. However, Mansfield, Loch, Henderson, Vicary, Cohn, and Young (1991) found that women who work in traditionally male professions experience sexual harassment more often than women who work in more traditionally female professions. In a study of sexual harassment among restaurant workers, Giuffre and Williams (1994) found that behaviors were more likely to be regarded as sexual harassment if the race of the perpetrator was different from that of the victim.

In contrast to the studies cited above, there have been several studies published which state that there is no significant difference between women of color and Caucasian women's experiences with sexual harassment. In a study conducted to examine the prevalence of sexual harassment in the Navy, Rosenfeld (1994) found that race and ethnicity played no role sexual harassment. Niebuhur and Boyles (1991) also investigated sexual harassment of military personnel and did not find any effects of ethnicity, gender, and previous experience on juror's judgements in sexual harassment cases. Ethnicity did not have a significant effect on the decisions made. So, it appears that there is conflicting evidence concerning the effect race may have on the incidence and reporting of and responses to sexual harassment. It is evident that more work needs to be done in this area before any conclusions can be drawn.

METHOD

Participants

Twenty students from an all female predominantly African-American college and twenty students from an all female predominantly white college between the ages of 18-24 participated in this study. Participants were paid for their participation and were treated in accordance with the "Ethical Principles of Psychologists and Code of Conduct" (American Psychological Association, 1992).

Apparatuses

Prior to the experiment, each individual was given a screening form and an informed consent form. The screening form identified medical conditions that would prevent individuals from participating in the study. The informed consent form was administered after an explanation of the nature of the study. The Medex NCCOM3 cardiac impedance system was used to assess heart rate. To obtain this measure, eight electrodes were placed on the neck and both sides of the body near the area of the xiphisternum. All signals were fed into the cardiovascular monitor and interfaced to a Radio Shack TSR 80 portable computer. Digital printouts of the cardiac measures were obtained through a Hewlett Packard printer. Blood pressure was assessed by the Ohmeda Fina Pres blood pressure monitor. The emotionally arousing stimuli used in the experiment were two scenes portraying sexual harassment and one neutral scene on videotape. One of the sexist scenes depicted an African-American woman being sexually harassed by her African-American male co-worker. Another scene depicted a Caucasian woman being sexually harassed by her Caucasian male co-worker. The neutral scene, which served as a control, depicted a rabbit running in a field at sunset.

Procedure

Upon entrance into the subject room, each participant was given a screening form and a consent form. After all of the participants questions were answered, the recording equipment was attached. After the presentation of each scene, the participants were asked to reflect on what they saw. They were asked to put themselves in the position of the victim and speak to the authority figure. Heart rate and blood pressure were measured as the participants viewed and reflected on two scenes depicting sexual harassment and a neutral scene. The measurements of heart rate and blood pressure were taken prior to the stimulus (pre-stimulus period), during the stimulus (stimulus period), while the subject was reflecting on the stimulus (reflection period), and while the subject was resting from the stimulus (post-stimulus). Each period, with the exception of the stimulus, lasted eighty seconds. The stimulus period lasted three minutes. Measurements were taken every twenty seconds throughout all periods. The averages of the measurements were used in the analyses.

RESULTS

T-test analyses were used to analyze ethnic group differences in heart rate and systolic and diastolic blood pressure reactivity to sexual harassment scenes. Hypothesis #1 (that there would be no differences in physiological responses to sexual harassment between African-American and Caucasian females) was not supported. African-American females had higher systolic blood pressure during the stimulus period of the white on white scene $t(15)=2.41$, $p=.029$. These individuals also had higher systolic blood pressure during the pre-stimulus period $t(15)=2.45$, $p=.027$, the stimulus period $t(15)=2.66$, $p=.018$ and post-stimulus period $t(15)=2.38$, $p=.032$ of the black on black scene. In addition, African-American females had a higher systolic blood pressures in response to both the white on white scene (collapsed across periods) $t=(15)=2.25$, $p=.040$ and the black on black scene (collapsed across periods) $t=(15)=2.37$ $p=.032$.

Hypothesis #2 (that there would be greater cardiovascular reactivity when the participants and the victim of the harassment are of the same race) was also not supported in that African-American females had higher systolic blood pressures to the white on white scene than their Caucasian counterparts (see the t value above). No significant differences were reported for heart rate or diastolic blood pressure.

DISCUSSION

The results of the study did not support the hypotheses presented. There were no significant differences reported for heart rate or diastolic blood pressure. Although there were no baseline differences for any of the physiological mesurements between the two groups, African-American females had higher systolic blood pressure during the stimulus period of the white on white scene and during the pre-stimulus, stimulus, and post-stimulus periods of the black on black scene. This finding shows that African-American women were more affected by the sexual harassment scenes. The heightened level of sensitivity by these individuals to this form of discrimination may be due to previous encounters with racial discrimination and harassment that African-American women experience. This finding is supported by Gruber and Bjorn (1982) who found that African-American female auto workers were more likely to be harassed on the job than their white female counterparts. In addition, the African-American women in their study reported experiencing racism more often than they experienced sexual harassment. The racial discrimination that these women encountered may have affected their responses to sexual harassment (Gruber & Bjorn, 1982). More research needs to be done in this area before any definite conclusions about ethnic differences in responses to sexual harassment can be made.

TABLE I

*Mean Systolic Blood Pressure Reactivity in African-American and Caucasian Female College Students

	African-Americans	Caucasians
Stimulus Period (white on white scene)	142 mm/Hg	109 mm/Hg
Pre-stimulus Period (black on black scene)	134 mm/Hg	105 mm/Hg
Stimulus Period (black on black scene)	141 mm/Hg	107 mm/Hg
Post-stimulus Period (black on black scene)	134 mm/Hg	106 mm/Hg
white on white scene (collapsed across periods)	139 mm/Hg	111 mm/Hg
black on black scene (collapsed across periods)	139 mm/Hg	110 mm/Hg

*Mean differences are significant at the $p < .05$ level

Peace Builders Case Study:
Combating Violence Through the Exercise of Positive Choices in an Elementary School in California

Charlotte M. Contreras

Department of Social and Behavioral Science

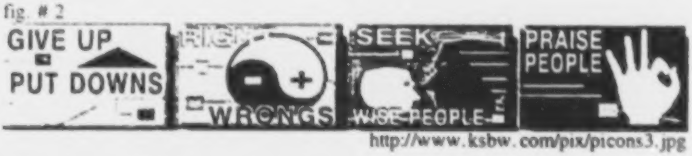
http://www.ksbw.com/pix/peace.jpg

Schools have been subject of social intervention programs for many years. Anti-violence programs have been playing an important role in deterring criminal activities in small communities and in society as a whole. Some intervention programs are created to teach a particular group of people positive and constructive life choices. They seek also to create productive members of the community.

INTRODUCTION

The study is based on a program referred to as Peace Builders. An intervention program combating violence while focusing on the practice of its four principles described below.

fig. # 2



http://www.ksbw.com/pix/picons3.jpg

The Objectives of the Study were to:
Determine the origin of Peace Builders Program.
Describe the purpose of the program.
Examine the implementation of the program
Establish the possible effects of the program in the children.

LITERATURE REVIEW

The Peace Builders program was created in Tucson, Arizona by Dr. Dennis Embry. The purpose of the program is to develop children's sensitivity towards positive attitudes through the practice of the following four main principles which are: praise people, give up put downs, seek wise people, and right wrongs/notice hurts. The

BEST COPY AVAILABLE

program is directed primarily at children from kindergarten through sixth grade. Peace Builders is an organized way to practice proven techniques (building blocks) in reducing violence. Although targeted at the children, the program requires the involvement of teachers, students, family, and the community as a whole. Everyone can contribute according to their capabilities as well as their individual positions in the community. The program teaches children, teachers, and other adults positive behavior skills which can be applied in many aspects of their daily life.

Peace Builders has been working in partnership with other programs with similar interests such as the VIPC (Violent Injury Prevention Coalition) which focuses on the prevention and decrease of violent acts and injuries in the City of Salinas California where this study took place. Peace Builders is a community implemented plan based on simple language "building peace" through the practice of the principles. Rather than "stopping violence" by enforcing unacceptable behaviors. It is a pro-active rather than a reactive language.

The effectiveness of the program in some part depends on the effort put into the implementation. When applied in schools, it is necessary to train all the personnel involved in the school in order to properly distribute the information and to practice its principles.

Dr. Dennis Embry mentioned in his review to this program, "that youth violence can be reduced dramatically over the next decade if communities apply the knowledge gained from this research to practices of parenting, day care, schooling, and adult role modeling." (The Community Awareness and Education Committee, Pg.7)

Because youth violence is such a problem in society, finding ways to reduce this social problem is necessary to ensure our schools' safety, as well as that of our communities. Dr. Embry's program allows everybody to contribute to the improvement and safety of society. The program is publicly recognized and available to everyone who wants to make a difference; all it takes is time and a little effort.

The study of intervention is based on the following: simply put children raised in violent surroundings, whether that violence is physical or emotional, suffer from and react to the disorder in ways that create more violence. This body of research shows that there are actual changes in the brain chemistry of children as a result of prolonged exposure to the stress of violence and abuse. These changes lead to depression, and anti-social behaviors. The surest way to reduce or stop this violence is to create family, school, and community environments which emphasize the following:

1) provide extensive positive models instead of negative models
2) reduce negative cues or threatening stimuli
3) show positive behaviors in many permutations to assure generalization of behavior
4) model coping actions (seeking help and problem-solving)
5) provide frequent opportunities to discuss and correct knowledge and actions
6) provide high rates of positive feedback for imitation
7) include many cues, prompts, or tools that facilitate generalization across time, people, behavior, and settings. (Embry, 1994)

METHODOLOGY

The research methodologies used in the research project was participant observation and ethnographic research. In face to face participation, the researcher visited an elementary school in Salinas, in which she interacted and participated with students at the 5th grade level within that school. The ethnographer incorporated the Peace builders program in the research project by actually delivering the program.

An example of field participation was to create case scenarios and to ask the children how they would use their Peace Building skills to solve a particular problem. The researcher would then engage along with the students in analyzing and discussing the responses in an interactive environment.

Every week the children were given a homework assignment in which they were to write down what they had experienced at home and on the streets. Explaining the situation(s), who they helped, how they solve the problem, how they felt about helping others, and how they found the situation to be related to what they have learn in the program. The purpose was to practice their peace building skills at home and at school to

BEST COPY AVAILABLE

write down everything they found to be related to what they had learned in the program. The following week, the children were asked to share their experiences with the rest of the class which enabled them to compare problems and solutions. I found this activity to be useful in the practice of the four main principles. Occasionally, the researcher would lead a discussion of the student's papers to the class. After the papers were reviewed, more case scenarios were given to the children to resolve issues concerning how they could implement their Peace building skills.

In other method of collection of data, the children were divided into three groups and organized in the construction of a Peace Building mural. Everyone participated in the creation of the mural by contributing his/her artistic talents. The purpose of the mural was to send a message of peace throughout the school. The children expressed their own ideas about Peace Building concepts through art. Students exchanged thoughts to be expressed in the mural in which the researcher was actively involved. This activity gave the researcher a chance to get to know the children on a more personal level and to establish a stronger rapport. Paints, crayons, markers, and glitter were used in the creation of the mural. Participant observation and group engagement were important methods in the collection of this data.

Along with participation, the researcher used ethnographic research which is the core methodological approach for the study of this research. The researcher needed to get a picture of the people in their natural settings. In doing so the researcher used emic (to find out how the group itself sees and categorizes its world) and etic (involves imposing categories developed outside the group) (Kane, Pg. 65) approaches of ethnography. The purpose was to get the students point of view of the program, and to interpret their responses. To get the point of view of the children the researcher would ask them questions about the program and whether or not they wanted to be Peace Builders. No structure questionnaire was used.

The researchers observed the children in the classroom setting taking notes on the interactions taking place. Discussion groups were conducted after every meeting in order to analyze findings.

THEORETICAL FRAMEWORK

The research was based on multicasual theories, all of which emphasized intervention strategies that give importance to praise, and positive actions, as opposed to pointing out negative behaviors.

Dr. Dinkmeyer and Dr.Mckay Wrote the book, "Raising a Responsible Child". In the book, the authors emphasized the point that psychological equilibrium is a product of need satisfaction. According to the book each individual has the following psychological needs:

1. To be loved and accepted
2. To be secure and relatively free of threat
3. To belong and to identify with a part of a group
4. To be approved and recognized for the way in which he/she functions
5. To move toward independence, responsibility, and decision making

Dinkmeyer and Mckay both conclude that,"..failure to feel and perceive self as accepted, loved, secure, approved, and responsible are forces that stimulate misbehavior." (Dinkmeyer, McKay Pg. 29).

It is on this premise that Peace Builders thrives .

The program applies its four main principles which, in turn, enforce positive aspects of behavior at all levels. These principles promote positive behaviors in the classroom and in the daily lives of students. Instead of having a list of don'ts, the classroom is filled with plenty of creative and productive things to do. This type of environment is conducive for the child to engage in more behaviors that are socially acceptable. While involved with the Peace Builders Program, children get positive attention thus their self esteem rises. This positive reinforcement allows children to build positive self images. All the new tools of coping acquired from the program go beyond the classroom. The children take the tools that they have learned and bring them on to the playground, into their homes, and to the community.

Parents learn that children react well to positive incentives; thus, the Peace Builders' principles become part of their home life. One of the children in the study drew a picture illustrating how her mother was arguing with her aunt. This particular child told her mother that she should notice hurts and right wrongs. This is a common example of how Peace Builders involves all sectors of the community. Exemplary behavior is recognized by the school every month. A Peace Builder of the month is recognized with an award presented to him/her in front of the entire school. Parents of the children are invited to the assembly and applauded for their participation.

CONCLUSION

It is the promotion of socially acceptable behaviors that encourages students to do the best that they can. Children want to feel accepted, approved, responsible, loved, and secure. These feelings are developed and nurtured in the Peace Builders Program. The study showed that the program's implementation on children in the fifth grade has had a positive impact. The program gave students a better understanding of cooperativism, team interaction, and positive behaviors. It allowed them to interact in a positive environment helping each other and understanding the benefits of positive self, responsibility, and accomplishment in doing so. Reducing the opportunities for misbehavior, the program encourages self respect, mutual respect, and non-violence. The smiles on the faces of the students, reduced incidents of violence on campus, and 100 percent participation by students are strong indicators that the program is working. More data will be gathered over the next few years by those following the progress of the program. An award dinner was held to honor Peace Builders by the City.

The Psychobiological Effects of Narcolepsy: Its Causes and Treatments

Sara Cronin

Department of Psychology
Syracuse University
430 Huntington Hall
Syracuse, NY 13244-2340

Dr. Charles Kutscher

The function of sleep has been a mystery for thousands of years. Scientific breakthroughs in the 1950s lead to the discovery of the physical components of sleep and its abnormalities resulting in the discovery of sleep disorders.

Narcolepsy is a sleeping disorder characterized by short episodes of rapid eye movement (REM) sleep numerous times throughout the day. The abnormal REM sleep pattern of narcoleptics is physiologically and psychologically problematic which have been shown to cause psychosocial damages. Current treatments for narcolepsy include psychostimulants such as dextroamphetamine and methylphenidate, but research on the effectiveness of these drugs have shown that until the exact physiological causes of narcolepsy are known, developing truly effective drug treatments is nearly impossible. A theoretical model for the pathophysiology of narcolepsy has been developed for the animal model for narcolepsy, and will help create a human pathophysiological model. Recent technological developments with sleep study equipment have made the future for studying the causes of physiological sleep mechanisms and narcolepsy very promising.

DESCRIPTION

Narcolepsy is a sleeping disorder characterized by uncontrollable sleep episodes at various times throughout the day. This uncontrollable onset of sleep is not caused by a lack of sleep from the previous night. From the sleep attacks that narcoleptics experience, it is apparent that rapid eye movement (REM) sleep is functioning abnormally.

Narcolepsy is the second-leading cause of excessive daytime sleepiness (EDS) diagnosed by sleep centers, following obstructive sleep apnea. Studies on the epidemiology of narcolepsy show that 0.2 to 1.6 per thousand in European countries, Japan, and the United States are affected, a frequency at least as large as Multiple Sclerosis and Parkinson's disease (Aldrich et al., 1994; Goswami and Thorpy, 1990). In the United States, approximately 200,000 people have narcolepsy, but only 50,000 are diagnosed.

The other symptoms of narcolepsy are cataplexy, sleep paralysis, and hypnagogic hallucinations. Cataplexy is a rapid loss of voluntary muscle control that lasts from a few seconds to 20 minutes. Cataplexy can be mild, and thus experienced as a buckling of knees, sagging facial muscles, nodding head, and/or loss of arm strength. More severe cases may cause a full physical collapse or a fall. Sleep paralysis is a mechanism that causes brief loss of muscle control when one is falling asleep or waking up. Although partially aware of the surroundings, people are unable to move and speak. Unlike cataplexy, sleep paralysis usually disappears when the subject is touched by another person. Hypnagogic hallucinations are very much like dreams, and usually involve images or sounds of strange animals or prowlers. They are often frightening because they are uncontrollable and waking up is not possible or seems far away. The dream-like experiences are

BEST COPY AVAILABLE

also disturbing because they can be mistaken for the hallucinations or delusions of mental illness.

Diagnosis of narcolepsy is confirmed at a sleep center through two tests: the Maintenance of Wakefulness Test (MWT) and the Multiple Sleep Latency Test (MSLT). Together these tests monitor how long it takes the subject to fall asleep at various times throughout the day and at night. The various stages of sleep are also recorded, and narcoleptics are identified by the short amount of time it takes for them to enter REM sleep. Normal sleepers usually enter REM sleep about ninety minutes after falling asleep, while narcoleptics usually enter REM sleep about five minutes after falling asleep.

Narcolepsy can be treated through behavioral modifications and drug therapy, although usually both are used for the best results. Behavioral therapy primarily consists of short naps taken thoughout the day. Drug therapy is based on stimulant medications sometimes combined with antidepressant medications; however, new and better types of drugs are being tested for improved efficacy in relieving narcoleptic symptoms.

Stimulant Therapy

Psychomotor stimulants produce behavioral activation usually accompanied by increases in arousal, motor activity and alertness. The three major classes of psychomotor stimulants include direct acting sympathomimetics, indirect acting sympathomimetics, and stimulants that have other mechanisms of action. Sympathomimetic compounds share similar molecular structures of a basic benzene ring with an ethylamine side chain attached, such as in betaphenethylamine from which amphetamine and methamphetamine are derived. Direct sympathomimetics include ephedrine which was the first drug used to help alleviate EDS. In 1935, Prinzmetal and Bloomberg tried using indirect sympathomimetics, and found that there were less peripheral side effects, lower cost and lower toxicity when compared to direct sympathomimetics.

Currently, indirect sympathomimetics are the best therapeutic stimulants that help alleviate EDS. Most of the indirect sympathomimetics that are available for clinical use focus on the dopaminergic system primarily, with a smaller effect on the adrenergic (norepinephrine) system. Indirect sympathomimetics act primarily by increasing the amount of monoamines available in the synaptic cleft by blocking the reuptake of, and enhancing the release of several neurotransmitters such as dopamine (DA), norepinephrine (NE), and serotonin (5-HT) (Aldrich et al., 1994).

There are two psychostimulants approved by the FDA to treat the excessive daytime sleepiness (EDS) of narcolepsy are indirect sympathomimetics--dextroamphetamine and methylphenidate. These drugs have an effect on the facilitory action of central catacholaminergic transmission and both dextroamphetamine and methylphenidate are the only two drugs that could bring MWT sleep latencies to approximately 70 percent of normal levels (see Figure 1) (Mitler et al., 1994). Although statistically and clinically significant therapeutic changes for dextroamphetamine, methylphenidate, pemoline, and modafinil were apparent (Mitler et al., 1994). In another study, methamphetamine had the greatest change on MWT sleep latencies when compared to dextroamphetamine and methylphenidate (see Figure 1) (Aldrich et al., 1994). Pemoline is another indirect sympathomimetic, but does not have as significant effect in treating EDS (Mitler, 1994). Modafinil is a stimulant that has a different mechanism than the indirect sympathomimetics, but seems to alleviate EDS as much as the other drugs, and with less sever side effects (Aldrich et al., 1994). Modafinil is the first drug in 20 years to reviewed by the FDA for treatment in narcolepsy.

The primary effects of indirect sympathomimetics appear to be on the dopamine systems in the CNS. The midbrain dopamine systems include two major pathways that project to different parts of the forebrain and appear to be responsible for the various aspects of psychomotor stimulant actions. The first mesocorticolimbic DA system projects to the ventral forebrain, including the nucleus accumbens, olfactory tubercle, septum and frontal cortex. The second nigrostriatal DA system arising from the substantia nigra, projects to the corpus striatum and the frontal cortex. These two DA systems are affected similarly by stimulants, suggesting that they could be working in the similar ways concerning neural cicuitry. Exactly which one of the two dopaminergic pathways is primarily involved in narcolepsy has not been determined.

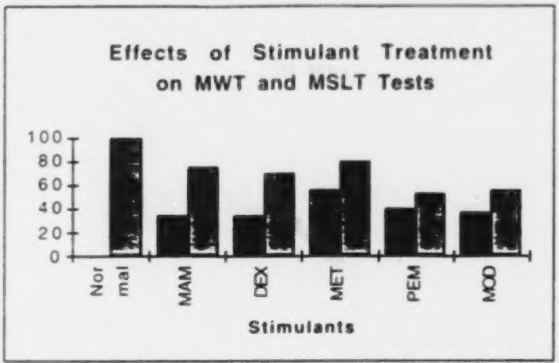

Figure 1: The darker gray corresponds to baseline percentage of sleep latency and the lighter gray corresponds to the stimulant treatment percentage of sleep latency compared to normal (for the MSLT normal is 13.4 minutes and for the MWT that is 18.9 minutes); MAM (Methamphetamine), DEX (Dextroamphetamine), MET (Methylphenidate), PEM (Pemoline), and MOD (Modafinil).

Antidepressant Therapy

Narcoleptics who suffer from cataplexy have been recommended to take tricyclic antidepressants which act primarily on norepinephrine (NE) and help prevent REM sleep onset. These drugs are usually taken in addition to the stimulants used to alleviate EDS. There are a number which have been tested for maximum efficacy, and there is little agreement among the experts for the best choices. Tricyclic antidepressants have been clinically effective in controlling hypnagogic hallucinations and sleep paralysis, the two less common symptoms in narcolepsy, but their mechanistic acton is still unknown (Aldrich et al., 1994). Most of the tricyclic antidepressants also have numerous side effects, such as dry mouth, anorexia, sweating, constipation, decreased blood pressure, and even drowsiness.

Imipramine seems to be one of the most documented anti-cataplectic agents. It acts as a potent inhibitor of NE uptake, with a minimal effect on DA uptake. Desimipramine and chlorimipramine have structures like imipramine and are used to treat cataplexy. All are prescribed for about 75-200 mg in daily divided doses (Goswami and Thorpy, 1990).

Protryptaline administered periodically at 15-60 mg/day is the United States' top anti-cataplectic agent (Goswami and Thorpy, 1990). Protryptaline is thought to help treat EDS, but is not effective in treating EDS when used alone. Protryptaline administered with indirect sympathomimetics such as methylphenidate or dextroamphetamine has proven to be clinically successful for those who experience EDS and cataplexy (Mitler and Hadjukovic, 1994).

REM SLEEP RESEARCH

Up to this point there has been little discussion of REM sleep, but it is the focal point when discussing the pathophysiological causes of narcolepsy. The unique feature of narcolepsy is that all the symptoms appear as a result of REM sleep intruding on waking function. Loss of muscle coordination also seems to play a role in narcolepsy since all of the symptoms are associated with it.

Narcolepsy is not the only abnormal REM sleeping disorder. Post Traumatic Stress Disorder (PTSD) and REM sleep behavior disorder (RBD) are two other abnormal REM disorders that would benefit greatly if the actual physiological components of REM sleep were known. Yet there has been little scientific study on the nature of REM sleep and dreaming. For abnormal REM sleep conditions, the best scientific pursuit of effective treatment is based solely on the physiological and anatomical knowledge of the function of REM sleep.

To determine the functional and neuroanatomical role of REM sleep is a difficult task to undertake with a lack of sufficient studies done on both roles. To accomplish these physiological and neuroanatomical goals, research must be conducted in two areas: through animal and human models.

Genetic Research

Doberman pinschers seem to have cataplectic episodes much like humans with narcolepsy that was first observed in the 1970s. A particular family of Dobermans was found with narcolepsy in 1977.

Over 84 litters of Doberman pinschers, Labrador retrievers, and mixed breeds have been bred at a Stanford dog colony through 1995. Dr. Mignot, the director of the Center for Narcolepsy at Stanford, has found that narcolepsy in Dobermans and Labrador retreivers is an autosomal recessive trait with full penetrance. Mignot's studies have shown that the canine narcolepsy gene is tightly linked with a gene that is highly homologous to the human immunoglobulin switch gene, strongly suggesting that the immune system plays a role in the development of narcolepsy. Since 1983 when researchers in Japan found that the human leukocyte antigen HLA-DR2 was common to those with narcolepsy, any attempt to identify another immune link to humans has failed. Specifically, the DQBI-0602 allele is found in 98 percent of narcoleptics, regardless of ethnic background, but 25 percent of the general population also has it (Mignot, 1996).

Another finding that only 17-25 percent of monozygotic twins are concordant with narcolepsy suggests that there are environmental factors neccessary to trigger the illness (Mignot, 1996). Additionally, about 1-2 percent of narcoleptics with cataplexy have a first degree relative that also suffers from the disorder. From these low statistics these data indicate that there are environmental and genetic components to developing narcolepsy.

Brain Research

Since recent technological advances have made noninvasive measurements of the anatomy of the brain possible, anatomical evidence can be combined with psychological examination of the human to understand symptoms and conditions of certain disorders.

Positron Emission Topography (PET) scan and Magnetic Resonance Imaging (MRI) are two developments that record the physiology of the brain in order to reveal how it is working. Similarly, the various stages of sleep are recorded by electroencephalograms (EEG) which are used at sleep

BEST COPY AVAILABLE

centers to confirm narcolepsy by timing SOREMPS (Sleep Onset REM Periods) by gauging the time it takes for the theta rhythm of REM sleep to occur. The EEG records when REM sleep is happening, but is not able to determine which brain structures are active.

A study combining the PET scan and EEG at the Cyclotron Research Center at the University of Liege in Belgium was the first study measuring brain activity during REM sleep. EOG and EMG (electro-oculogram and electromyogram respectively) recordings of the subjects were also taken (Maquet, 1996).

This was the first comprehensive study assessing the structures active in REM sleep in humans (Maquet, 1996). The original thirty males involved in the study was diminshed to seven because the men had to show certain sleep behaviors that would allow the machines to accurately record the data. These sleep behaviors could have unintentionally selected a particular type of sleeper which would have an effect on the results. Better technology making subjects more comfortable and the tests easier to record will improve the validity of the results.

The PET-EEG results showed that the regional cerebral blood flow was positively correlated to REM sleep in the pontine tegmentum, left thalamus, both amygdaloid complexes, anterior cingulate cortex, and right parietal operculum. The study concluded that given the role of the amygdaloid complexes in the acquisition of emotionally influenced memories, the pattern of activation in the amygdala and the cortical areas provides a biological basis for the processing of some type of memory during REM sleep.

There were also negative correlations between regional cerebral blood flow and REM sleep in the dorsolateral prefrontal cortex, the parietal cortex, the posterior cingulate cortex and the precuneus. Less blood flow to the prefrontal cortex is logical since it is the area that is most active in conscious states, whereas during sleeping which is an unconscious act, it would make sense that the prefrontal cortex is inactive.

This is the first time the role of the amygdaloid complexes has been shown to be involved in REM sleep (Maquet, 1996). The abundant activity of the amygdaloid complexes suggests that the dreaming that occurs in REM sleep is emotionally based, and could be a release of stored emotion gathered during the day. It may be that given the role of the amygdaloid complexes in the acquisition of emotionally influenced memories, the pattern of activation in the amygdala and the cortical areas provides a biological basis for the processing of some type of memory during REM sleep. Much more research confirming the results from this study need to be done in order for the amygdala involvement in REM sleep to be validated.

The amygdala is also connected physiologically to the onset of canine narcolepsy. From Dr. Mignot's research there has been recorded neuronal degeneration localized in the lateral nucleus of the amygdala and in the medial septal nucleus of the narcoleptic canine. The onset of this degeneration begins about one month prior to the onset of symptoms and only lasts about two months (Mignot, 1996). The degree of degeneration is 100 percent more than the degeneration in normal dogs (Mignot, 1996). The onset of the degeration takes place at about two months of age. Coincidentally most human narcoleptics begin showing symptoms between the ages of 10 and 25, usually during adolescence.

While PET brain scans show active brain structures, MRI brain scans are much more detailed and accurate. Up until very recently it was impossible to combine the EEG and MRI in order to record the brain structures active during REM sleep. The EEG shows when REM sleep is occuring, and the MRI shows what brain structures are active, but both could not be combined.

Data on sleep fMRI was presented at the Harvard Institute of Medicine by Dr. Jeffrey Sutton on April 7, 1997. The audience was very receptive to the new technology allowing for the combination of the EEG and MRI in order to see which brain structures are active during sleep. The analysis of the first tests done with the fMRI are not yet complete, but frontal changes (mostly deactivation), cingulate, parietal, and temporal changes seem to occur as non-REM sleep progresses. Brain regions activated during REM sleep are the amygdala and V1, otherwise known as Area 17 of the primary visual cortex. This is a strong indication that the amygdala is definitely activated during REM sleep because both the PET scan and the fMRI have found it to be activated.

The PET study and the EEG-fMRI technological advancement are the types of human studies that are needed to determine the functional neuroanatomy of REM sleep. While these studies have only begun determining the neuroanatomical function of REM sleep, once that is known, then the cause of narcolepsy and its abnormal REM sleep mechanism is that much closer.

Racial Similarity, Cost to Helper, and Sex as Determinants of Helping Behavior

Heather A. Dooner and Margaret M. Blake

Department of Psychology
Iona College

Faculty Advisor:

Patricia Oswald

The purpose of this study was to examine how racial similarity, cost to helper, and sex would affect the likelihood of eliciting altruistic responses. Two hundred forty resumes were left at public telephones. Attached to the resumes was a picture of the applicant, which conveyed information as to the race (White vs. Black) and sex of the individual, a self-addressed envelope which either had a stamp affixed to it (no cost to the helper), or no stamp (cost to the helper), and a cover letter indicating that the resume must be mailed immediately. Racial similarity was manipulated by the location the letter was left in (predominantly White neighborhood vs. predominantly Black neighborhood). A loglinear analysis was performed on the frequency of resumes returned. As predicted, delivery of the resume was facilitated more when there was no cost to the helper. Females were assisted more than males when the altruistic response entailed cost to the helper. Individuals from the predominantly White neighborhood assisted the White applicant more than the Black applicant, and individuals from the predominantly Black neighborhood assisted the Black applicant more than the White applicant. This finding suggests that racial similarity is a factor affecting altruistic behavior. No other findings were significant.

INTRODUCTION

Altruism refers to acts that suggest an unselfish concern for the welfare of others. If it can be determined which factors influence an altruistic response in individuals, the probability of receiving help in the future can be increased.

Implications of altruistic behavior include motivations of "social responsibility, guilt reaction, dependency, obligation, reciprocity, modeling, and reinforcement" (Tipton & Jenkins, 1974, p. 209). The introduction of a cost to helper variable has been found to suppress the reinforcing value as motivation to help. Thibaut and Kelley's (1959) economic theory of social interaction states that the relative cost to and reward to the individual will determine how an individual will behave in interpersonal situations. An overwhelming decrease in altruism has resulted as cost variables are implemented. In a study done by Wagner and Wheeler (1969), altruism was examined in terms of generous versus selfish models and high versus low cost levels of helping. The low cost level facilitated both the generous and selfish models, while the high cost inhibited both. Similar results are found in a study done by Tipton and Jenkins (1974) in which response cost on the acquisition of instrumentally conditioned helping behavior was studied. In this study, slower responses, indicating less altruistic behavior, were found across trials involving a cost, as opposed to no cost, variable. These findings strongly suggest that cost to a potential helper is one of the strongest deterrents in altruistic behavior. Few studies, however, have examined the strength of the cost variable in relation to racial similarity.

Race and its effect on altruism has been studied and reported in several different ways. The most frequent analysis of the effect of race on altruism involves observing which race is helped most overall. A study done by Bryan and Test (1967) examined the influence of a solicitor's race on the donation behavior of shoppers. It was found that "the Negro solicitor elicited a statistically significant lower percentage of donors than did the Caucasian" (Bryan & Test, 1967, p. 405). The variables of interpersonal attraction and avoidance from contact with a minority group member were attributed to the basis of difference in donation behavior.

One of the more famous studies of the late sixties and early seventies was the dropped wallet experiment. The first study, done between 1966 and 1968, found that Whites tended to return the "lost" wallet more frequently to Whites. Blacks, however, did not show a preference for returning a found wallet to other Blacks (Hornstein, 1976). This study was replicated in the early seventies, yielding a slight shift in results. Whites continued to favor Whites, but this time more Blacks returned the wallet, and there was a tendency for them to return wallets to other Blacks more frequently than to Whites. It appears that a new black consciousness had emerged. The present study considers essentially the same phenomenon; with a prediction that this consciousness has continued, and has even grown.

The effect of sex on altruism has been focus of many previous studies. Most earlier studies found that females were helped more than males (Colaizzi, Williams, & Kayson, 1984; Feinman, 1978; Gentile, Naughton, & Kayson, 1986; Mallozzi, McDermott & Kayson, 1990; Sileo & Kayson, 1988; Simon, 1971). Colaizzi et al. (1984) reported that stranded female motorists when dialing a wrong number and had no money or change to make another phone call, upon asking the person to call another number for them, received assistance more rapidly than males. Gentile et al. (1986) performed a similar experiment using the stranded motorist with no means of making another call, and found similar results. Mallozzi et al. (1990), also experimenting with a similar situation, found that fewer cars passed a stranded female motorist than a male in the same predicament. Sileo and Kayson (1988), found that women making annoying phone calls were listened to longer than men.

The purpose of this study was to examine how racial similarity, cost to helper, and sex of the person in need of help would affect the likelihood of eliciting altruistic responses. It was predicted that more altruistic responses would occur when there was no cost to the helper, when the victim was of the same race, and when the victim was a female.

METHOD

This experiment involved the researchers "accidentally" losing 240 resumes. The resumes, depicting an applicant pursuing a career in marketing, were left at public telephones in lower Westchester County, New York. Attached to the resume was a picture of the applicant, which conveyed information as to the race (white or black) and the sex (male or female) of the applicant. The physical attractiveness of the applicants was relatively equal, determined by independent raters. There was also a cover letter attached to the front of the resume written by the applicant to his or her mother stressing that the resume must be mailed immediately. In addition, there was a self-addressed envelope that was either stamped or not stamped. If the envelope had a stamp affixed to it, there was no cost to the helper. If there was no stamp, there was the cost to the helper of having to supply the postage. Racial similarity was the fourth variable manipulated in this study. Racial similarity was manipulated by the location the letter was left in (predominantly white neighborhood or predominantly black neighborhood). The socioeconomic status of these two areas was relatively equal.

Fifteen resumes were distributed for each of the 16 possible combinations of the four independent variables. Helping consisted of facilitating the delivery of the resume. Therefore, the dependent variable was the frequency of resumes returned, indicating an altruistic response. Coding on the

BEST COPY AVAILABLE

inside of the envelope enabled the researchers to determine the combination of the independent variables of each resume received at the address depicted on the envelopes.

RESULTS

A loglinear analysis yielded likelihood ratio chi squares on the frequency of resumes returned. A 2 (sex) x 2 (race) x 2 (location) x 2 (cost to helper) design produced a significant main effect for cost to helper, $\chi^2(1) = 56.93$, $p = .0000$. Delivery of the resumes was facilitated when there was no cost to the helper at a rate of 45.1% as opposed to 7.3% when there was the cost of supplying a stamp. There was an interaction between race and location, $\chi^2(1) = 6.59$, $p = .0103$. Delivery of resumes belonging to the white applicant was facilitated more by individuals in predominantly white neighborhoods ($n = 29$) than by individuals in predominantly black neighborhoods ($n = 15$). Delivery of resumes belonging to the black applicant was facilitated more by individuals in predominantly black neighborhoods ($n = 24$) than by individuals in predominantly white neighborhoods ($n = 14$). There was also a marginally significant interaction between sex and cost to helper, $\chi^2(1) = 2.72$, $p = .0990$. When the elicitation of an altruistic response entailed cost to the helper, females ($n = 7$) were assisted more than males ($n = 2$). The overall rate of helping, determined by the number of resumes returned, was 34.2%.

DISCUSSION

As was hypothesized, delivery of the resume was facilitated more when there was a stamp on the envelope, indicating no cost to the helper, than when there was a stamp on the envelope, indicating that delivery of the resume required the helper to supply the postage. This is consistent with previous research (Shotland & Stebbins, 1983; Tipton & Jenkins, 1974; Wagner & Wheeler, 1969). In an experiment by Shotland and Stebbins (1983) which used a "wrong" telephone number as the method of investigation, it was found that when participants were implicitly asked to look up one telephone number, they were more likely to assist the individual in need of help than when they were asked to look up five telephone numbers. Looking up five telephone numbers as opposed to looking up one is of greater cost to an individual not only financially, but it also requires more time. When asked to drive a confederate to a location that is near (low cost) as opposed to a location that is relatively distant (high cost), individuals will help the confederate in the low cost condition most often (Shotland & Stebbins, 1983). In the present study, the absence of a stamp required the altruistic participant to supply postage, which only costs 32 cents. However, for the individual who does not carry stamps with him or her, there is also a time factor involved of having to go out of one's way, for example, by waiting in line at the post office to buy a stamp. When there was a stamp on the envelope, the participant need only place the resume in the envelope, seal it, and drop it in the nearest mailbox. There are other possible reasons for the cost difference in the present study. There is the prospect that the participants assumed that the person who lost the resume may come back looking for it. It is also possible that upon noticing there was no postage affixed to the envelope that the participants decided to leave it at the telephone booth, assuming someone else would come along and see that it was delivered.

The hypothesis that females would be assisted more than males was not confirmed in the present study. However, a marginally significant interaction was found between sex and cost to helper. Females were assisted more than males when the altruistic response entailed cost to the helper. This suggests that individuals are more likely to go out of their way to help a female than they are to help a male, or that females are assumed to be more in need of help.

It was also hypothesized in the present study that there would be an interaction between race and location, suggesting racial similarity in helping behavior. This hypothesis was confirmed. Individuals from the predominantly White neighborhood assisted the White applicant more than the Black applicant, and individuals from the Black neighborhood assisted the Black applicant more than the White applicant. Previous studies showed that White participants helped White individuals more than they helped Blacks, but there was no racial difference in the helping behavior of Black participants (Gaertner & Bickman, 1971). In early studies done by Hornstein (1976), the same results were evident. This suggests racial prejudices in the helping behavior of Whites, but no racial prejudices in the helping behavior of Blacks. Clark and Clark (as cited in Hornstein, 1976) investigated the doll preferences of young children, finding that Black children often preferred White dolls to Black ones, suggesting a preference of the majority outgroup over one's ingroup. However, later studies by Hornstein (1976) indicated a shift in the results. Whites continued to help other Whites more than they helped Blacks, but Blacks this time helped other Blacks more frequently than they helped Whites. This may be the result of the emergence of a new Black consciousness. It may also be a way for Blacks to cope with the discrimination they have suffered, by they themselves discriminating against a race that in our culture has shown to prejudge minorities. Another implication for this finding is the suggestion that individuals are more attracted to and tend to associate with others who are similar to them physically and share the same attitudes. This also carries over to helping behavior, with individuals helping others who are racially similar to themselves more than those who are different.

In conclusion, the effects of racial similarity, cost to helper, and sex were examined in the present study. Cost to helper affected the likelihood of eliciting a helping response, with the delivery of resumes being facilitated more often when there was no cost to the helper. Sex was marginally significant when it interacted with the cost variable, with females being assisted more than males when the helping response entailed cost to the helper. Racial similarity was another significant factor affecting helping behavior, with individuals embodying helping behavior more for individuals of their own race than others. Further research of racial similarity in helping behavior should also consider the possible effects of sex and race. The present study explored the sex of the individual in need of help, but the sex of the helper was not controlled. In a society where interracial relationships are increasing, and negative and even perhaps positive, attitudes about interracial dating and marriages exist, there may be an inclination for individuals to help others of another race only if they are of the opposite, or perhaps the same, sex.

Sex Role Type and Effectiveness of Women Speakers at a Religious Presentation

Catherine E. Dundas

Department of Behavioral Sciences
East Texas Baptist University
1209 N. Grove
Marshall, TX 75670

Faculty Advisor:

Dr. Lynn New

This study measured the perceived effectiveness of women speakers in making a religious presentation. Three basic sex-role types:1) masculine, 2)androgynous, and 3) feminine were presented to four independent groups of college students who were asked to rate speaker effectiveness. Masculine and androgynous speakers were preferred over feminine religious speakers. A feminine education speaker was preferred over feminine religious speaker.

A study of Fortune 500 companies found that women comprise 3.6% of board members and only 1.7% of senior executives (Morrison & Von Glinow, 1986; Sachs, 1992). There appears to be a bias against women in upper level executive positions. Why are women such a minority in this arena? Not only are women underrepresented in business, but also in religious leadership positions (Barna, 1993). The Catholic faith provides women the opportunity to serve in convents and some denominations allow women to preach. However, in the Southern Baptist Convention, the majority of vocational ministers are men. Is this because so few Southern Baptist women are motivated to seek leadership positions or is there a verifiable influence from structural factors?

Women as Managers

Researchers have been interested in the issue of women as managers and conducted experimental research to address questions of perception (Greenglass, 1993; Burke, 1994). At first glance, research results seems to suggest that there is not a significant difference between the ratings of male and female leaders (Shein, 1975; Hawkins, 1995; Eagly, 1995). However, included in these findings are two conditions that seem to be necessary to support the conclusions. One condition is that men are rated more effective at typically masculine tasks, and women at typically feminine tasks (Shein, 1975; Eagly, 1995). The inverse is also true, meaning that women and men are rated less effective at "cross-sex" tasks.

Organizational Hierarchy

A second condition Shein mentions is that the perceived

BEST COPY AVAILABLE

effectiveness of the leader is dependent on the context and organizational hierarchy, or power structure (Ely, 1995; Shein, 1975). Ely's findings show that the strength of traditional stereotypes is inversely related to the number of women in senior level positions. In the present study, the Southern Baptist Convention will represent the organizational hierarchy in which few women hold leadership positions. The study of the women in SBC life is an important element for the future of the denomination. One important difference between the business world and the religious world is the aspect of scriptural authority. The religious world seeks to operate under the principles found in the Bible. There are verses of the Bible that seem to discount women in authority, however, interpreters continue to debate whether the discount is based on scriptural authority or tradition (Miles, 1983).

Sex-typed Roles

Bartol suggests that the concept of masculinity and femininity are dynamic, and changing as societies change. However, some stereotypes persist across generations. Women are generally considered more nurturing, understanding, gentle, and suited for tasks that require such traits. Men are typically achievers, tough, protective, and more suited for intitiating tasks (Bartol, 1976). Sandra Bem has designed a measure for masculinity and femininity. She added a third category, that of the androgynous person, an individual that has both masculine and feminine qualities (1974).

Men can be typed feminine and women can be typed masculine. Either can be androgynous. In the realm of management, androgynous and masculine types have been found to be more likely to emerge as leaders in group situations (Kent, 1994). Kent found that sex-type was a better predictor of leadership than gender. Therefore, a woman that can perform a masculine task using traditional male behaviors may be considered a more effective leader than a woman that performs in a more feminine way.

Extending previous research, the present study will examine the effectiveness of women in religious leadership roles. It will follow Burke's (1994) study of women managers except for the change of setting to a religious task rather than a task in the business world. The tasks of a religious leader, such as a pastor, include many areas, but this study will consider the verbal preaching task only.

Hypotheses

It is hypothesized that androgynous and masculine sex-typed women speakers will be rated more effective at a religious presentation than feminine sex-typed women speakers.

Secondly, feminine sex-typed women speakers will be rated more effective at a non-religious presentation than a religious presentation.

METHOD

Subjects

The subjects were 57 college freshmen in introduction to psychology classes receiving extra credit for participation. 70% of the subjects were 18 and 19 years old, and 30% were between 20 and 36. Thirty seven females and nineteen males participated.

Instruments

Bem's (1974) Sex Role Inventory (BSRI) uses the common perception of traits associated with masculinity, felinity, and androgyny. The sixty item test requires that subjects place the words they consider descriptive of themselves in a certain column. The purpose of the instrument is to suggest a certain gender-role type for an individual, not necessarily dependent on biological sex.

This master list of terms was used to design mock resumes and "reference letters" to be given to subjects as the first manipulation of the independent variable. This instrument also helped provide guidelines for the second manipulation, the speaker video.

The dependent measure that was used is an unpublished, objective five-point questionnaire for speaker effectiveness. The nature of the present study necessitated the construction of a relevant measure of leader effectiveness.

Procedure

Subjects were randomly assigned to four groups. Each group viewed a corresponding video. The four groups viewed masculine, androgynous, feminine religious, and feminine educational videos, respectively. The task of the subjects was to help select a speaker for the week-long chapel services. They were to watch one video and rate the speaker on effectiveness. Subjects reviewed the materials mentioned above, a resume, portion of a reference letter and a video clip. The hobbies and reference items were adjusted for the various sex-types of the three groups. The adjusted items followed characteristics listed on Bem's sex-role descriptions.

In order to test hypothesis two, concerning the feminine non-religious presentation, the Ss in the fourth group performed the task of selecting a Public Relations director for a new elementary school. The resume and letter were altered to account for this in the categories of "doctorate", "minor", and "hobbies".

In the second stage of treatment, the Ss viewed the video clips. One model performed all four clips to control for speaking ability. The speaker performed the same presentation each time behind a pulpit, except for the educational clip in a classroom. The speaker's dress and manner were adjusted in each clip to convey sex-role types. Androgyny consisted of casual attire such as blue jeans. The speaker was to be truthful, sincere, likable, and tactful. The Masculine dress was a pants suit. No make-up or jewelry was used. She was instructed to be aggressive, forceful, athletic, and competitive. The third and fourth presentations were alike in dress and manner, feminine. The speaker wore a dress, full make-up, hair and jewelry, and she conveyed a manner of soft-spokenness, compassion, warmth, and sympathy.

After viewing the video, each group received the appropriate questionnaire. The subjects then completed the task of evaluating the speaker effectiveness. A brief personal information section followed.

RESULTS AND DISCUSSION

Hypothesis one predicted that masculine(1) and androgynous(2) groups would have higher group means on question #6 "I would select this speaker" than feminine religious group(3). A tukey-HSD test conducted between groups 1, 2, and 3 found that pairs 1,3 and 1,2 differed significantly,($p<.05$). The sujects indicated a score between 0 and 4 on question #6.

Table 1: Tukey-HSD Group Means Comparison

Mean	Group	3	1	2
0.928	Feminine			
1.631	Masculine	*		
1.800	Androgynous	*		

Hypothesis two predicted group four (feminine education) to have a higher mean than group 3 (feminine religious). The results of an independent t-test of group means demonstrated a higher score for group 4,(p<.001).

Table 2: Independent Groups T-test for Feminine Groups 3 and 4

Group	N	X
Religious	14	.929
Education	9	2.556

t=(-5.77), p=.000

A manipulation check asked the subjects to indicate whether they perceived the speaker as "more feminine than most women" or "more masculine than most women". The group means of the two questions were compared with-in groups. Group one (masculine) had a mean shown to be significant, (p<.001). The other three groups had no significant differences of the means.

Hypothesis one predicted that masculine and androgynous speakers would be preferred over a feminine religious speaker. This was stongly supported by the data, (p<.001). A speaker needed a score of 3 or 4 to be selected for the task, chapel speaker for the week. None of the four roles rated the speaker either a 3 or 4. Groups 1, 2, and 3 rated the speaker less than a two. However, of the first three groups, masculine and androgynous had higher group means on question #6 than the feminine religious, which did not even have a mean above 0.

According to hypothesis two, the feminine education speaker should have been preferred over the feminine religious speaker. This also was strongly supported by the data. Group 4 (feminine education) had no religious connections and the group mean was the closest to selecting the speaker.

The subjects had an opportunity to explain further whether or not the speaker should be selected. The most frequent comments indicated that the speaker spoke in an elementary manner, did not have enough passion, and would not appeal to a college audience.

One important element of the research was successful manipulation of the sex-role type on the speaker video. The results indicate that this happened. Only group 4 (feminine education) saw the speaker as more masculine when she was intended to be more feminine. Also important is that this group was found to have given the speaker the highest group mean of all four groups.

Implications

Results of this study suggest that a woman is rated more effective at a traditionally accepted role and less effective at the "cross-sex" task. Clearly, the subjects did not approve of the woman in a preaching role, but had less of a problem with her educational leadership role. Women of all sex types were considered more suitable for the traditionally feminine task. The organizational hiearchy of religious leadership is pre-dominantly male, therefore, strong stereotypes about women's roles are evident.

These results suggest that if a woman behaves in a more traditionally masculine pattern, she may be more likely to be accepted at a masculine task. Even when acting in the more masculine role, a woman is likely to find herself mistrusted and fighting this bias. The ideal of a "calling" in ministry is that one follows the inner sense they feel about the directions for his or her life. Ministry is a lifestyle of service in which one endeavors to help those that are hurting. The results suggest the existence of a bias toward women preachers that discourages those with sense of calling to serve in such a vocation. Often scripture is used to argue against women in leadership, but no scriptural reasons were offered by the subjects. Perhaps biased practices are based on tradition rather than scripture.

The traditional forms and methods of ministry will not work in the next century. The shape of the country and religious society begins now for the future. Researchers can help prepare people for changes, especially in the area of women's issues. Further studies and scriptural examination could encourage the progress of women in ministry.

ALPHA-GANZFELD

An Experimental Study on Alpha Rhythms Under the Ganzfeld Condition

Darin Dutcher and Joshua Johnson

ABSTRACT

There has been interest in relaxation while under the Ganzfeld condition. The Ganzfeld condition consists of a subject receiving a constant stimuli in one or more senses. It has been suggested that the Ganzfeld condition aids relaxation (Sargent, 1982); however, this has not been reliably demonstrated. It is known that visual input is, although not exclusively, a determining factor in alpha blocking (Bohdanecky 1984). This study intended to empirically examine the relationship between the Ganzfeld condition and relaxation.

A within-subjects experiment measured electroencephalogram (EEG) rhythms on participants who experienced relaxation under normal conditions versus the Ganzfeld condition. The Ganzfeld condition consisted of the participants receiving static visual and auditory input (Braud, 1975). The control group experienced normal relaxation involving sitting motionless for the same amount of time without the Ganzfeld stimuli. It is possible that the introduction of the experimental variables would cause less eye movements; therefore, increasing alpha activity (Bunnell, 1978). It was hypothesized that more alpha rhythms (see Appendix A) will be detected under the Ganzfeld condition than under the control condition.

METHOD

Participants

Thirty eight students participated, but only thirty three subjects' data were used due to equipment malfunction during certain trials. The subjects consisted of fifteen males and twenty three females in the eighteen to twenty-four year old age group of college students who attend Hamline University. Time spent for the experiment was compensated with extra credit to be used for psychology courses.

Design and Procedure

The subject sample was randomly divided into two groups for this within-studies experiment by having each subject experience conditions in the reverse order of presentation relative to the previous subject. Group A participated in the experimental setting first and then participated in the control setting. Group B participated in the control setting first and then participated in the experimental setting.

The subjects were divided into two groups to offset any feeling of anxiousness or discomfort caused by the novelty of EEG recording that might have affected ability to relax during the first few minutes of the study. In this way, any ordering effects should have been counterbalanced.

Both the control setting and the experimental setting consisted of the subject sitting in a chair inside an enclosed bright room. In addition, the subject was monitored for cortical alpha rhythm activity by an EEG recorded by Super Scope software. The electrodes were placed on the scalp according to the 10-20 system of electrode placement. The subject was read a prologue (see Appendix B) on how to relax to this situation and remained in this environment for a period of eight minutes after the prologue was read. Two 1000 ms EEG recordings of the subject were taken under each condition at four minute intervals.

The experimenters introduced the influence of Ganzfeld through use of halved white ping pong balls placed over the subjects eyes. White noise was provided by previously recorded radio static (Braud, 1975). The white noise was introduced to help drown out any auditory distractions during the experimental eight minute segment.

After each subject had experienced both conditions, a debriefing statement (see Appendix C) was read and any questions were answered.

The recorded alpha rhythms were independently calculated for frequency by each experimenter. The frequency of the alpha rhythms were determined by counting the number of waves starting from crest to crest or trench to trench depending on the experimenter. Alpha rhythms were discriminated from beta and theta activity by noting that an alpha rhythm must not have a frequency of less than 35 ms and an amplitude difference of no greater than 10 mv. The mean score between the experimenters' results were then added into the database. The results from the EEG's were analyzed in a two tailed T-test for paired samples with a p of .05 or less.

RESULTS

There was no significant difference between the control condition and the experimental condition.

DISCUSSION

The results revealed no significant differences between the control and the Ganzfeld condition. Some subjects reported feeling more uncomfortable under the experimental condition than under the control. Also, some subjects reported having trouble relaxing in general. These reports may point to possible confounding variables in the study. Other factors that may have influenced the results could have been noises in the classroom next door to the lab and occasional hallway vacuuming that could have been heard even over the white noise. The introduction of white noise noise for the experimental condition could have been more aggravating than soothing and relaxing, thus tainting the data. It is also possible that the subjects were anxious to get out of the study because many subjects ran during the day were in between classes and meetings. In addition, the very state of being attached to an EEG monitor might have introduced confounding variables (e.g., anxiousness, feelings of discomfort). For future research it may be recommended to either test subjects who are not in a rush, or to shorten the length of the test.

Careful consideration and time must be spent in order to eliminate these possible data corruptions. No firm conclusions should be drawn from a study of this nature without the presence of ideal conditions. Ideal conditions are those that have eliminated the possible confounding variables discussed earlier.

Appendix B

PROLOGUE

You will experience a series of relaxing sessions for this experiment. There will be a break between each session. For each session we ask that you focus on your breathing, become aware of it and focus on every inhalation and exhalation. Try not to let your mind wander and detour you from your focus on breathing. We also ask that you do NOT shut your eyes any long periods of time. When I shut this door, you may begin your relaxation session and I will open the door when the first session is over.

Appendix C

DEBRIEFING STATEMENT

Thank you for your participation in this study, your help is greatly appreciated. Your name will be given to the instructor you have chosen for extra credit. All data will be kept confidential as there might be publicational and/or educational uses for these results. If you have any further questions regarding this study, you may contact the supervising faculty member, Dr. Dietrich at 641-2333.

THE RELATIONSHIP BETWEEN THE EXTENT TO WHICH ADOLESCENTS ARE TAUGHT NOT TO TRUST STRANGERS DURING CHILDHOOD AND INTERPERSONAL SKILLS

Laurie Harrier

Department of Psychology
University of North Texas
P. O. Box 13587 UNT Station
Denton, TX 76203

Faculty Advisor:
Dr. Francis Terrell, Ph. D.

This study examined the relationship between being taught not to trust strangers during childhood and interpersonal skills among adolescents. A total of 106 male and female college students and their parents were administered a background information questionnaire, the Revised UCLA Loneliness Scale, the Self-report Trust Scale, the Interpersonal Competence Questionnaire, and the Social Avoidance and Distress Scale. Late adolescents, ages 18 to 21, who were taught as children not to trust strangers displayed higher levels of social anxiety and lower levels of emotional support. Females tended to have higher levels of social avoidance and mistrust relative to males regardless of whether they were taught not to trust strangers during childhood.

Background

In response to the perceived increase in the number of abductions and molestations, many parents have decided to educate their child about his safety. The safety rules that parents teach not only contain information about how their child can protect himself, but also the message that strangers are not to be trusted. In teaching a child that strangers are not trustworthy, the parents are not allowing their child to learn the importance of trust. Erikson (1955) points out that trust is fundamental to further psychological development as well as future interpersonal skills. According to Erikson these children who fail to develop a "basic" sense of trust during the early years will view the world as hostile in later life. Also, these children will most likely develop into insecure individuals with low self-esteem who feel lonely, isolated, and unloved (Mitchell, 1990).

Unknowingly, by teaching children not to trust strangers, parents may be eroding the basic foundation for future interpersonal relationships. Trust is where all interpersonal relationships begin, whether it is with strangers or loved ones, and without a foundation of trust cooperation, planning, caring, and sharing cannot be developed (Mitchell 1990).

Given that trust is the basis for all interpersonal relationships, it is necessary to clarify how "trust" is defined. On a broad scheme, trust is defined by Deutsch (1973) as the confidence that one will find what is desired from another, rather than what is feared (Rempel, 1985). While on a more personal scheme, Rotter (1980) defines it as a generalized expectancy held by an individual that the word, promise, or statement of another individual can be relied on (Rempel, 1985). Studies done by Into (1969); Katz & Rotter (1969) show that this barrier of who or what people trust develops over the years mainly from watching what their parents say and do. By modeling their parents, children learn the basic of self-disclosure. According to Jourard (1958), self-disclosure is the process of making the self known to others. Studies done by Snoek & Rothblum (1979) show that the structure and child-rearing practices of the family do influence self-disclosure, by providing a model for interpersonal relationships. Their studies also show that a child who is taught to disclose thoughts and feelings at home will generalize to others (Snoek &Rothblum, 1979). Jourard (1959) claims that the amount of disclosure that a person is willing to disclose could be seen as a measurement of the closeness of a relationship. In turn, the closeness could also be seen as an indicator of the amount of trust between two people (Jourard, 1959).

Intimacy, according to Erikson (1963), is the capacity to commit (one)self to concrete affiliations. Intimate relationships are characterized by openness, sharing, and

794

mutual trust (Raskin, 1986), and are shown in varying degrees by three manifestations: verbal, nonverbal, and physical. Each manifestation is comprised of different levels. For example, physical manifestations range from a casual handshake to sexual fireworks, while verbal manifestations are measured in the amount of self-disclosure (Lowenthal &Weiss, 1976). Therefore, if what Jourard says is true, that self-disclosure is able to measure the degree of trust in a relationship, then trust, self-disclosure, and intimacy must be interrelated. A person cannot have an intimate relationship without some form of trust which is displayed through the amount of self-disclosure.

Studies done by Raskin (1986); and Orlofsky, Marcia, & Lesser (1973) show that trust, self-disclosure, and intimacy are interrelated as well as hierarchial. Trust is the basis for the other two; however, the three cannot exist without each other. Therefore, if one of these concepts is influenced, either negatively or positively, by another then the interaction of the two could either hinder or help the end product. Based on this, then if a child lacks trust in strangers then his ability to become intimate with others could be seriously hindered in turn causing him to become isolated, depressed, and to have low-self esteem. Thus, the present study looks at the effects on young adults'/ late adolescents' intimacy caused by teaching children at an early age not to trust strangers. If the young adults were taught not to trust strangers, then they should be more likely to be depressed, show an increased feeling of loneliness, show a lack of trust in others, and generally be low in interpersonal skills.

Method

Subjects

Subjects were 210 young adults between the ages of 18-21. The sample consisted of an equal number of girls and boys. Subjects also were 210 primary caregivers, with each young adult having one to represent him/her. All the young adults were psychology volunteers who received extra credit upon the completion of all the questionnaires.

Measures

Both the primary caregiver and the student filled out a background questionnaire designed to determine what and how they were taught about strangers. Also, each student filled out four questionnaires: The Lagace & Gassenheimer (1989) Trust and Suspicion Scale, the Hays & DiMatteo (1978) UCLA Loneliness Scale, the Cole & Milstead (1969) Social Avoidance and Distress Scale, and the Buhrmeister (1990) Adolescent Interpersonal Competence Questionnaire.

Trust and suspicion: The Lagace & Gassenheimer (1989) Trust and Suspicion Scale is a ten-item questionnaire measured by a four point Likert scale. It was used to measure trust and suspicion by self-report.

Loneliness: UCLA Loneliness Scale-Revised is a twenty-item questionnaire measured by a four-point Likert scale. It was used to measure the subject's level of loneliness.

Anxiety: Social Avoidance and Distress Scale (SAD) is a twenty-eight item questionnaire measured by the subject choosing either true or false. It was used to measure the level of anxiety that the subject experiences in social situations.

Competence in interpersonal skills: Adolescent Interpersonal Competence Questionnaire (ICQ) is a forty-item questionnaire measured by a five-point Likert scale. It was used to measure the subject's interpersonal competence.

Procedure

As mentioned previously, college students and their primary caretakers were asked to participate in this project. Participants were recruited by visiting introductory psychology courses and asking students to volunteer. Those who volunteered were informed that in order to receive experimental credit, they needed to obtain consent from the individual who was responsible for raising them during the first five years of their life to agree to fill out a background questionnaire requiring approximately thirty minutes. Only the data from those students whose biological mother or father was responsible for raising them was used. Students and care givers were asked to fill out the questionnaires without consulting each other.

After the questionnaires of both the student and the care giver was returned, those care givers and students who indicated that they were taught not to trust strangers were used to form one group. Similarly, only those students and their care givers that were taught to trust strangers were used to form a second group. Thus, where disagreement existed between students and care givers regarding whether they were taught to trust strangers were not included.

Results and Discussion

The data was analyzed by using a 2x2 (gender x trust vs. mistrust) MANOVA. The independent variables consisted of males vs. females and whether adolescents were taught by parents to trust strangers during childhood. The outcome measures consisted of scores on The Interpersonal Competence Questionnaire (ICQ), The Social Avoidance and Distress Scale (SAD). The means and standard deviations on all scales are presented in Table 1.

Table 1
Means And Standard Deviations For All Groups On All Measures

	High Trust				Low Trust			
Measures*	male		female		male		female	
	M	S.D.	M	S.D.	M	S.D.	M	S.D.

* SAD=Social Avoidance Scale, ICQ=Interpersonal Competence Questionnaire, In=Initiation, NA=Negative Assertion, Dis=Disclosure, ES=Emotional Support, CM=Conflict Management

Significant differences were found for the main effects of both trust (Wilk's Lambda (2, 101= .006; approximate F=5.48, p<.05) and gender (Wilk's Lambda (2, 101= .004; approximate F=5.86, p<.05). Univariate F tests and studentized t-tests were next used ti identify specific group differences. Significant differences were found as a function of whether adolescents were taught to trust on the SAD (F(1, 102)=10.75, p<.05). Significant differences were found as a function of gender on the SAD (F(1, 102)=6.98, p<.05); Emotional Support subscale (F(1, 102)=22.01, p<.05).

Protected t-test analysis revealed differences between the females that were taught not to trust strangers (x=42.54) versus those who did not receive training (x=44.00) on the SAD (p<.01). Additionally, differences were found between females who were not instructed by their caretakers (x=44.00) and males taught not to trust strangers (x=40.75) on the SAD (p<.001). Also, females taught not to trust strangers (x=42.54) had higher scores than males taught not to trust strangers (x=40.75) on the SAD (p<.01). Additionally, males taught not to trust strangers had lower scores (x=40.75) than males who did not receive instructions not to trust strangers (x=42.89) on the SAD (p<.02).

796

This study was taken to explore whether a relationship exists between the extent to which children were taught not to trust strangers during their childhood and their interpersonal skills during late adolescence. Our hypothesis that children taught not to trust strangers had poorer interpersonal skills as late adolescents, was supported. Adolescents who were taught as children not to trust strangers had higher levels of social anxiety and lower levels of emotional support. Overall females who were taught not to trust strangers displayed higher levels of social anxiety while males who were taught not to trust strangers had lower levels of emotional support.

One unexpected finding was that females tended to have higher levels of social avoidance and mistrust relative to males regardless of whether they were taught not to trust strangers during their childhood. However, this finding is consistent with previous research (Block, 1973). Heretick (1981 & 1984) found that college females tended to be less trusting than males. These authors theorized that the reason for these differences might be that parents tend to teach their female children to be less trusting in general, than boys. Thus, the significant differences found in this study as a function of gender may have been due to the fact that females are less trusting rather than simply being taught not to trust strangers. Although differences were found as a function of whether adolescents were taught to trust strangers, this study does have several limitations. Most important, our sample consisted of white, middle-class students residing in the southwest. Had adolescents of different ethnicities residing in other geographical regions participated, different results may have been obtained. Thus, additional research should be conducted prior to drawing any conclusions.

Assuming that future research is consistent with our findings, our results may have both practical and theoretical implications. At the theoretical level our results could lend support to Erikson's eight stages of development.

At an applied level, our results may also have some implications for child rearing practices. For example, parents might wish to consider modifying the instructions they give their children regarding trust of strangers. The parents might want to consider treating their children more androgynously. They might want to raise their girls to believe that competiveness, risk taking, and trusting others are acceptable in today's society. For boys, parents might want to raise them to believe that in today's society it is acceptable to be loving, emotional, and trusting. Parents might also want to consider guiding their children into activities that, today, are considered to be geared toward particular sexes.

Dr. Cynthia Crown

Relationships among eating attitudes, loneliness, and self-monitoring in male and female college students were explored. The surveys used included the EAT-26 (Garner & Garfinkel, 1979), the UCLA Loneliness Scale (Russell, Peplau, & Ferguson, 1977), and the Snyder's Revised Self-Monitoring Scale (Lennox & Wolfe, 1983). Significant relationships were found between: (a) four factors of the EAT-26 Scale (dieting attitude, awareness of food content, food preoccupation, and total score); (b) between dieting attitude and ability to modify behavior; (c) between EAT total score and ability to modify behavior; and (d) food preoccupation and loneliness. Strong relationships were found between eating attitudes and self-monitoring, yet, a very strong relationship did not exist between eating attitudes and loneliness.

INTRODUCTION

Research on eating patterns has shown that they can change for a number of reasons, especially during the college years. Hesse-Biber and Marino (1991) conducted a study on women making the transition from high school to college to see if there were any changes in their self-concepts or eating patterns. Their study found that college students experience significant changes in their transition from high school to college. The results showed a pattern of diminishing self-concept over time and revealed a connection between self-concept and eating problems. They found that those participants who remained or became abnormal in eating patterns showed a pattern of diminishing self-concept over time compared with the participants who remained normal or got better.

Studies on loneliness have shown that when college students feel lonely they tend to withdraw more into themselves by participating in solo activities, which could include eating, as suggested by Ondercin's (1989) study that found a relationship between compulsive eating and loneliness. The goal of Ondercin's study was to determine the characteristics behind binge eating. It was found that high compulsive eaters reported significantly more frequent eating in response to unpleasant emotional states, such as boredom, loneliness, sadness, anxiety, and anger, than either the medium or low compulsive eaters. These results support past research that found eating is a response to negative affect and may have a stress-reducing function (Ondercin, 1989).

Studies on self-monitoring show that behavioral intentions and attitudes play a large role in actions, as found in a study conducted by Prislin and Kovrilja (1992). The results of their study support the idea that "low self-monitors tend to regard their attitudes as relevant guides to actions. In contrast, high self-monitors tend to form their behavioral intentions by relying on their perception of what relevant others think of whether or not they should perform a certain behavior" (Prislin & Kovrilja, 1992, p.1136). These findings suggest that both loneliness and self-monitoring can be related to eating attitudes. In the present study, it was hypothesized that there are strong correlations between loneliness and eating attitudes, and self-monitoring and eating attitudes.

METHOD

Participants

The participants in this study were 51 undergraduate students (18 male, 31 female and two who failed to indicate their sex) at Xavier University in Cincinnati, Ohio.

The average age of the participants is 19. Participation was strictly voluntary and all APA ethical guidelines were followed.

Materials

Three different scales were used to measure personality attributes of the participants in the present study. The first scale, the Eating Attitudes Test (EAT-26) (Garner & Garfinkel, 1979), included 20 items from the original 26 on the EAT-26. Five questions on body image and one demographic question were omitted, because they were irrelevant to the present study. The questionnaire is scored using a Likert scale ranging from zero (rarely) to three (very often). The scale is scored using the sum of the responses. The questionnaire measures four different factors: (a) dieting attitudes; (b) oral control; (c) awareness of food content; and (d) food preoccupation. Using Cronbach's coefficient alpha, the determined reliability of this scale was r=.83, and the test has concurrent or criterion validity (Koslowsky, Scheinberg, Bleich, & Solomon, 1992).

The second scale, the UCLA Loneliness Scale (Russell, Peplau, & Ferguson, 1977), included 20 items to determine the degrees of loneliness in the participants. The items were answered using a Likert scale ranging from one (never) to four (often). The scale is scored using the sum of the responses. The UCLA Loneliness Scale is fairly reliable with a "test-retest correlation over a two-month period of r=.73" (Russell et al., 1977, p. 292).

The last scale, the Snyder's Revised Self-Monitoring Scale (Lennox & Wolfe, 1983), contained 13 items and was answered using a Likert scale ranging from (false) to five (true). Scores are developed from the sum of the answers. This scale is "face valid and has enough internal consistency to merit further examination" (Lennox & Wolfe, 1983, p. 1363).

The data for this experiment was collected in several different group settings. The participants were first given a consent form to read that explained the basic design of the experiment. After signing the consent form, they were given a questionnaire containing the three scales stapled together in a particular order. They were told not to spend too much time on one answer, because their responses would be more valid when based on their first reactions. The participants then placed their completed questionnaires into a folder to assure anonymity.

RESULTS

The means and standard deviations for EAT factors one through four, EAT total score, loneliness, ability to modify behavior and sensitivity to others are found in Table 1. Inspection of this table indicates that females have higher means in every category, but large differences between males and females occurred in only half of the categories. In dieting attitudes, females have a mean score of 8.10, while males have a mean of 3.67. In the EAT total scores, the females have a mean score of 17.77, while the males have a mean score of only 9.11. There were no significant differences between the scores of males and females of the Self-Monitoring scales or the loneliness scale.

Correlations between variables are presented in Table 2. Inspection of the table indicates that the following relationships were statistically significant: (a) dieting attitude and awareness of food content; (b) dieting attitude and food preoccupation; (c) dieting attitude and EAT total score; (d) dieting attitude and ability to modify behavior; (e) dieting attitude and sensitivity to others; (f) awareness of food content and food preoccupation; (g) awareness of food content and EAT total score; (h) awareness of food content and ability to modify behavior; (I) food preoccupation and EAT total score; (j) EAT total score and ability to modify behavior; and (k) food preoccupation and loneliness.

DISCUSSION

The findings of this study show strong correlations between four of the factors on the EAT-26 Scale, which is to be expected since they are included within the same scale. The strongest of these correlations are between dieting attitude and EAT total score with r=.94, between awareness of food content and EAT total score with r=.79, and between dieting attitude and awareness of food content with r=.68. These results suggest that an individual who has a high score on dieting attitudes and/or awareness of food content would also have a high EAT total score. The results also suggest that an individual with

800

a strong dieting attitude would be aware of the content of food that is eaten. The third factor of the EAT-26 Scale, oral control, was not found to be strongly correlated to any of the other factors of the scale. This may suggest that oral control is not related to the other factors on the scale and should not be included on the EAT-26.

Dieting attitude is found to be correlated with both self-monitoring scores, ability to modify behavior and sensitivity to others. This finding supports Hesse-Biber and Marino's (1991) study on self-concept and eating disorders. They found that dieting attitude has a relationship to how individuals think they are perceived by others. Both awareness of food content and EAT total score are correlated with ability to modify behavior. This correlation may mean that individuals with high EAT scores are able to adjust the amount of food they intake.

As was hypothesized, a correlation was found between eating attitudes and loneliness. The study shows a correlation of $r=.37$ between food preoccupation and loneliness. This correlation is not a very strong correlation, but it does suggest a relationship between giving too much time and thought to food and feeling lonely. The correlation is not strong enough to suggest a causal relationship but further research in this area could provide that information.

Some problems in this study include the limited generalizability of the participants. Because Xavier is a private, Catholic institution, this study is not representative of all college students. Other problems arise from the fact that females make up nearly 61 percent of the participants in this study, which could present some gender biases. Also, sophomores make up nearly 55 percent of the participants, while only 25 percent of the participants are from the freshman or senior classes. Having so few subjects from the freshman and senior classes could have limited the findings of the study. Hesse-Biber and Marino's (1991) study found that eating attitudes change during the freshman year and are different in the senior year. Thus, had more participants from these two classes been included stronger correlations may have been found.

Another problem with the study is that not every item on the EAT-26 Scale was included. Five questions concerning body image and one demographic question were omitted, because they were irrelevant to the present study. This may affect the reliability and validity of the scale and the results.

Further research should be conducted in the areas of eating attitudes and loneliness before causal relationships are suggested. The research should also include participants that better represent the population being studied. Also, all items on the EAT-26 could be used to ensure reliability and validity.

Overall, this study was somewhat effective in examining the hypothesis. The findings did indeed show correlations between eating attitudes and self-monitoring, as well as a relationship between eating attitudes and loneliness. However, the correlations were not very strong. Thus, more research should be conducted on these three factors before further conclusions can be drawn.

Faculty Advisor:

Dr. Lauren F. V. Scharff

We are depending more and more on computers everyday. We can receive our mail, read our newspapers and magazines, do our research and shopping all on our computers. The Internet is greatly responsible for these capabilities. Today, anyone can make a website and have it put on the Internet. The result of this freedom may often be very creative webpages, but also frequently hard to read webpages. Many novice designers may feel that if they can read their display, so can everyone else. This can be a problem, especially when the designers are young and the readers are older. More specifically, younger viewers usually manage to read even the worst video display terminal (VDT) designs, but this is not always true for the older readers (>45 years) or those with a color-perception deficiency (colorblindness).

Legibility, and in turn readability, of the VDT is very important for efficient communication. Legibility depends on many factors: color combinations, background texture, font, font size, word style (bold, italicized, etc.), computer pixel size, along with many others. There are plenty of opinions, preferences, observations, and even proposed algorithms related to legibility, but very little published, objective data that directly relates to webpage style screen displays. Despite the small amount of objective data, several legibility factors are acknowledged by books discussing on-screen displays. Unfortunately there is often little, if any, agreement across different publications. For example, although many of the design books do agree in their recommendations for "high contrast," there is very little agreement regarding other variables that influence good screen design.

Contrast is very important in any written text. Whether in print or on screen displays, low contrast can be irritating and fatiguing to young readers, but for older readers and the colorblind it can be impossible to read. Contrast is the value (intensity) difference between two areas; the value is the amount of lightness or darkness in a color. For example, black on white has a high contrast, while black on gray has a lower contrast. There is much confusion when discussing contrast and color. Saturated green (little white light) on saturated red has a very low contrast, but green on red could have a high contrast. For example, one can place a fully saturated green on a red that is almost pink by adding white light.

Also, when discussing color, one must acknowledge difficulties when presenting information using short wavelengths (i.e. blues). First, short wavelengths have lower resolution because they are blurred by the ocular media, and there is lower sampling by the cone mosaic. Thus, readability of any text presented in short-wave light will be decreased. Second, it is inadvisable to mix colors that are on the extreme ends of the color spectrum (i.e. blues and red). When the spectrally extreme colors are mixed they quickly fatigue the eyes, because these wavelengths have different focal lengths. Reds have long wavelengths, and they are focused farther back in the eye, unlike blues which have short wavelengths and are focused closer to the middle of the eye. This causes a sort of 'tug of war' in the eyes between focusing on the red and focusing on the blue. (For an excellent discussion of human color vision and how it affects computer displays, see Galitz, 1994).

For the novice designers, contradictory information in books written for professional designers can pose difficulties for their design process. For example, Powell (1990) suggests "avoid sharp contrast between foreground and background...," but Rivlen, et al. (1990) suggests "choose a text colour/background colour combination which maintains a high contrast..." Dumas (1988), warns us to stay away from "placing shades of blue beside each other," yet in another text, cyan text on a blue background is listed as a good color combination (Rivlin, et al, 1990). One text even listed such foreground/background color combinations as green on red, "bright white" on white and yellow on white as "good choices" (Powell, 1990). Powell also said that black text on white background was only acceptable "when used in a limited area;" however black on white has been the most recommended color combination found across all books. Pace (1984) found that blue on white had low error rates, but Powell regards blue text as a "poor choice." These are just a few of the many contradictions that can be found in design books. These contradictions are very confusing and quite overwhelming, and make it difficult to answer a simple question such as "what colors do I use on my webpage?" Even worse, what if someone only refers to one book (which most people would do), and that one book is the one that suggests green on red or yellow on white?

BEST COPY AVAILABLE

Information on paragraph style, word style, and font type of VDT's is a little harder to come by than information on color and color combinations; but fortunately this information is less contradictory and less vague than that regarding color use. Most of the information on font type and style came from research using printed text on paper. VDT design books still refer to this research. However, Kruk and Muter (1984), found that text displayed on VDT's is "20-30 percent slower" to read than printed text (reading speed is used to infer legibility).

Regarding paragraph style, left justification is favored to right justification. Justification simply means to be lined up, and text can be either lined up on the left margin, right margin, both or neither (if text is centered). Trollip and Sales (1986) found a 10% increase in reading time with text that was both justified. This finding was attributed to "uneven spacing between words and/or frequent hyphenation;" plus, right justification makes it harder for a reader to find their place when they lose it (Dumas, 1988).

Several word style factors (letter case, bold, italicized, etc.) may also affect readability. For example, text displayed in mixed upper and lower case letters is faster and easier to read (Tinker, 1963). This increase in speed is due to a person's tendency to recognize the shape of the word as opposed to each individual letter in a word. When text is in all upper case letters, it takes away the characteristic shape of words. The reader is forced to identify the individual letters of each word, which slows the reader down.

Additionally, font type can affect readability, depending upon if the letters contain serifs or have proportional spacing. Serifs are the little marks at the end of letter strokes; hence, serif fonts have serifs and sans serif fonts do not have serifs. Some examples of serif fonts are Times New Roman and Courier New, and an example of sans serif font is Arial. There is some contradictory research regarding the use of serifs. Horton (1990), warns against serif fonts in smaller font sizes, but Tinker (1964) says that fonts with serifs can be read more easily. Much of this contradiction comes from the generalization of research conducted for legibility of text on paper, to the legibility of text on VDT's.

Finally, letter spacing, proportional or non-proportional, can influence readability. A non-proportional font gives the same amount of space for an 'i' that it gives for an 'o,' while proportional fonts give an 'i' a smaller space than an 'o.' Courier New is a non-proportional font, and Times New Roman and Arial are proportional fonts. Helander et al. (1984) found that proportionally spaced type is read faster than "fixed-width" font.

As mentioned earlier, there are very few objective studies published on this topic, especially with respect to interactions among the factors which influence readability. It is not feasible to test every combination of variables, and since there has been so little prior research, we will start with a few basic variables: foreground/background color combinations, font type, and word style. The foreground/background color combinations chosen for this experiment are black on white, yellow on blue, black on gray, white on blue, green on yellow, and red on green. Times New Roman (Times NR), Courier New, and Arial were used for font type, and italicized and Roman (plain) were used for word style. The current experiment placed these variables in a webpage style design in order to be more generalizable. Due to previous research we predicted that text with higher foreground/background color contrast would have faster reaction times. Text written in plain word style and sans serif proportional font were also predicted to have faster reaction times. Overall, it is predicted that as legibility increased, reaction time would decrease. Although interactions of some sort are expected, no particular trends are predicted.

METHODS

Participants

Forty-three participants were included in the current experiment. All participants except two, the advisor and the experimenter, were naive to the hypotheses. All participants were tested for normal color-vision, and all participants had 20/20 or corrected to 20/20 vision. Participants were informed of the required procedure and completed a consent form.

Apparatus

Macintosh Power PC 7200/120 computers were used in the experiment. The stimuli were created in B/C Power Laboratory (an experiment application), which also presented the stimuli and collected the data. Data analysis was performed using Statistica (a statistics application).

Stimuli

A nation-wide Internet survey was used to help chose the foreground/background color combinations (for the results of this survey, refer to http://www.thecube.com/color/). Six color combinations were selected: yellow on blue (Y/BL), white on blue (W/BL), red on green (R/GN), black on gray (BK/GY), black on white (BK/W), and green on yellow (G/NY). These color combinations were chosen for a few basic reasons. First, basic colors that are available on most monitors were selected. Second, the experimentor selected two light on dark color combinations (W/BL and Y/BL), two dark on light color combinations (BK/W and GN/Y); the fifth color combination, red on green, is not easily classified as light or dark. Finally, black on gray was chosen because it is commonly used on webpages. The RGB value of the colors used in this experiment are as follows: red-R(56797), G(0), B(0); blue- R(0), G(0), B(56797); yellow- R(65535), G(65535), B(0); green- R(0), G(34952), B(0); gray-R(30538), G(30538), B(30538); black- R(0), G(0), B(0); white- R(65535), G(65535), B(65535).

Within each color combination, there were three font types (Arial- sans serif/proportional; Courier New- serif/non-proportional; Times NR- serif/proportional), and within each color/font variation, there were two word styles (italicized and plain). Thus, there were six font/word style variations within each color combination. Each font/word style combination within each color combination was presented five times, so that there were thirty trials per color combination, and a total of 180 trials in the experiment.

Thirty text stimuli were presented in each color combinations. Within each color combination condition the thirty texts were counter-balanced across each of the font type/word style combinations. More specifically, the text stimuli consisted of thirty text excerpts that were imported from the Internet into B/C Power Laboratory. The thirty text pages ranged in length from 130 to 150 words (some text were edited to fit within the word range). A target word was placed within each text; the placement was carefully randomized across all trials. At the bottom of each stimulus screen, there were five shapes that corresponded to each of the five target words (circle, triangle, star, diamond, and square).

Procedure.

All participants were screened for normal color vision. Then, they read instructions on the computer screen, and they signed their consent form. They were given ten practice trials, and they were allowed to ask questions at any point throughout the experiment. The order of the practice trials and the 180 actual trials were randomized by the computer.

Participants were instructed to scan a screen of text and find a target shape word. Once they found the target word, they clicked on (using the mouse pointer and mouse) the corresponding shape at the bottom of the screen. The start of each trial was self-paced, and each trial ended when the participant clicked the target-word shape. Participants were instructed to respond as quickly and accurately as possible. It took participants anywhere from 45 minutes to 2 hours (average time was one hour) to complete the experiment. After the experiment, all participants were debriefed.

RESULTS

The data were sorted by each variable for each participant, and the mean for each condition was calculated (only RT's from correct responses were used). All participants with an overall accuracy rate of at least 95% were used. However, the data of two of these participants were not used due to RT patterns that implied that they were not diligently attending to the task. Figure 1 illustrates means for all conditions.

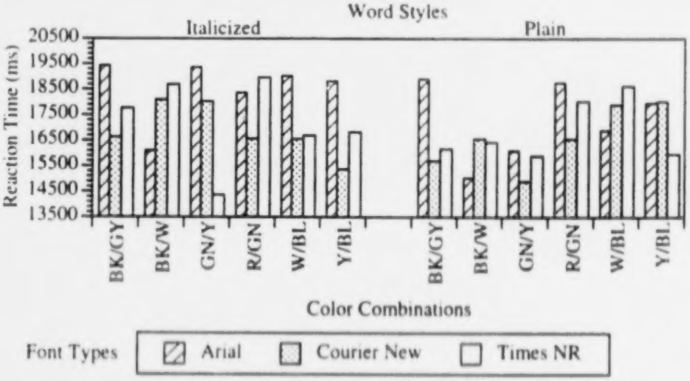

Figure 1: A 3-way interaction between color combinations, font types, and word styles. Notice how the performance on one variable is dependent on other variables.

Results of a 3-way with-in groups ANOVA showed a significant main effect of color combination (F (5,200) =2.27, p<.05). GN/Y had the fastest RT (x=16457.98), and R/GN had the slowest (x=17894.07); all other color combinations fell between with close RT's. Times NR font type (x=16746.87) was significantly faster than Arial (x=17700.85; F (2,80) =3.19, p<.05).

There was a significant two-way interaction between color combination and font type (F (10,400) =3.07, p<.001); GNY/Courier New (x=15252.84) and GNY/Times NR (x=15411.96) had the fastest color/font interaction RT's, with GNY/Arial (x=18709.13) and RGN/Courier New (x=18883.66) having the slowest RT's. The reaction time of other font types also depended upon color combination. The interaction between font type and word style was also significant(F(2,80)=5.25, p<.01). Arial/italicized (x=18517.42) was significantly slower than Times NR/italicized (x=16637.74), Times NR/Arial (x=16856), and Arial/plain (x=16884.28).

Finally, there was a significant three-way interaction between color combination, word style, and font type (F(10,400)=3.25, p<.01; see Figure 1). These results show that there is no one font or one color combination to use, but rather there are certain fonts that work better with certain color combinations. Although word style shows some interaction with other variables, generally plain word style is faster than italicized word style. An interest in the black on gray color combination developed once the data for the experiment was analyzed. Black on gray is the default for a popular Internet browser, and the question was posed if black on white would be a more "user friendly" color combination.

In an attempt to answer this question, a control experiment was setup to compare black on white to black on four variations of gray. The colors combinations used were black (RGB=0) on white (RGB=65535), black on light gray (RGB=56797), black on medium gray (RGB=48059), black on dark gray (RGB=30538), and black on very dark gray (RGB=21845). "Medium gray" is the Netscape default, and "dark gray" is the gray used in the original experiment. This experiment used the exact same setup as the previous experiment, with the exception of not using Courier New font type, and 10 of the 30 text selections were eliminated. There were twenty-one participants, and it took them thirty minutes to one hour to complete the experiment. The means for each condition are illustrated in Figure 2.

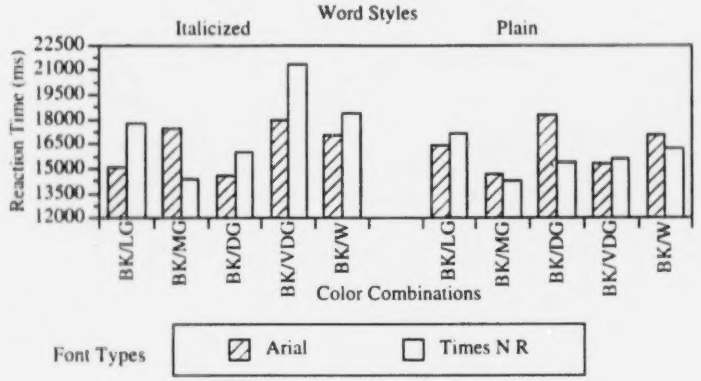

Figure 2: Means for all conditions (gray combinations, font types, and word styles). Plain text conditions are significantly faster than italicized. Again, performance on one variable is dependent on the other variables.

Surprisingly, black on medium gray (x=15215.21) and black on dark gray (x=16088.70) had significantly faster RT's than black on white (x=17176.3; F (4,80)=3.37, p<.01). Plain word style (x=16052.53) was still significantly faster than italicized (x=17025.69; F (1,20)=5.22, p<.03), and unlike before, there was no significant difference between the two fonts. There were significant two-way interactions between color combinations and font types (F(4,80)=2.46, p<.05). Times NR had more variability across color combinations than did Arial font type. The medium gray/Times NR combination had the fastest RT (x= 14350.80), yet very dark gray/Times NR had the slowest RT (x=18505.95). There were also significant interactions between color combinations and word styles (F(4,80) =3.06, p<.02). Very dark gray/italicized had the slowest RT (x=19647.46), and medium gray/plain (x=14497.40), and dark gray/italicized (x=15347.57) has the fastest RT's.

DISCUSSION

As predicted, significant main effects and interactions were found for font type, word style, and color combination. For example, plain text is consistently responded to more quickly than italicized. These main effects suggest that one can make general recommendations to screen display designers. However, the significant interactions highlight the fact that there is no one color combination, font type, or word style to use, but rather all conditions affect one another. In Figure 2, compare the results of Arial/italicized to Arial/plain. Notice how within each of the gray combinations, the results "flip-flop" between italicized and plain. This type of interaction was true of other variable combinations across conditions, which means a designer must consider a variable's influence on all other variables. This interaction of variables is not mentioned in current manuals; hopefully, future manuals will address such interactions.

From these results, one can say that contrast affects legibility, but unfortunately, it does not seem to be as simple as high contrast being better than low contrast. In the main experiment, GN/Y had the fastest RT's, and in the control experiment, medium gray, and dark gray had the fastest RT's. In neither experiment did the BK/W condition show the fastest RT's. These results show that these participants had faster response times when more median contrasts were used. These results supported Powell (1990), who suggested avoiding sharp contrasts, but did not fully support Rivlen et al (1990), who suggested maintaining high contrast.

According to a manual by AT&T (1989), the direction of the contrast (dark on light, or light on dark) might also affect legibility. When light text is placed on a dark background the text may seem to glow and become blurred; this is referred to as halation, and it may make the text harder to read. Some evidence for an effect of halation was found in the current experiment. The mean RT for light text on a dark background was $x=17559.24$, while the mean RT for dark text on a light background was $x=16909.33$. This finding might also be attributable to a subject experience factor due to the frequency of dark text on light backgrounds; more research is needed on this topic before any strong recommendations can be made.

Several of the contradictions discussed in the literature review were addressed in this experiment. Powell (1990) suggested the color combination of red on green, and warned against black on white. Yet in the main experiment, red on green was found to be the worst color combination, and black on white to be one of the best. The results show significant main effects between the serif and sans serif fonts; which supports Horton (1990) and Tinker (1964). However, the results contradicted those of Helander et al. (1984), who found that proportionally spaced font was faster. In this experiment, Times NR (proportionally spaced) was faster than Courier New (non-proportionally spaced), while Arial (proportionally spaced) was slower than Courier New. There is no simple explanation for all the current findings, but, hopefully this research and further research on this topic can and will be beneficial to webpage designers.

The Relationship Between the Protestant and Catholic Religions and Guilt

Caramin C. Johnson

Minneapolis, MN 55408

Faculty Advisor:
Emily Hause

The theological and philosophical differences between Catholic substance and Protestant principle are well documented. The attitudes and belief systems propagated by each have much to do with the way guilt is perceived by individuals within these two styles of worship. The hypothesis of this study is that Catholics have higher guilt scores than Lutherans, and higher religiosity results in more guilt. Thirty nine college students completed a Situational Guilt Scale and a Religion Scale. In partial support for the hypothesis, higher religiosity scores correlated with higher guilt scores for Lutherans, r=.58, p=.006. Discussion will focus on limitations of the sample and implications for understanding these results.

BACKGROUND

The theological and philosophical differences between Catholic substance and Protestant principle are well documented. The attitudes and belief systems propagated by each have much to do with the way guilt is perceived by individuals within these two styles of worship.

The Protestant principle involves the idea of questioning everything. It takes no definite form, except the Gospel, and encourages free thought. It contains ambiguity, relativism, diffusion and autonomy. Protestant scholars have tried to wrestle with the possibility of autonomy within the realm of Christian thought (Adams, 1965). The implication here is that humanity has been granted a certain autonomy by God and if given enough insight a person could control one's own destiny, to sin or not to. The concept of sin from an autonomous standpoint questions the legitimacy of guilt and the acknowledgment of the judgment. If a person commits an act that is deemed sinful by the church, others, or oneself, then additional emotions or behaviors may be acknowledged as guilt. With rational thinking and individual focus these issues can be easily addressed. The idea here is that the aim of Protestantism is to not get caught up in the means but instead to look toward the purpose, Heaven.

Catholic substance, on the other hand, has definite content and form. There is certainty, absolutism, and foreclosure (Adams, 1965). Catholic church rules are designed to alleviate guilt through penance, and to further this concept, the act of forgiveness is administered through a church official. Faith in its rituals may give Catholics a propensity to dwell on their sin and guilt. Since it is true of Catholic life that a person need not commit a sinful act to be a sinner, and just the thought of such acts are transgressions unto themselves, then this seems to be the inherent psychic dilemma for the Catholic faith. An unquestioning devotion to the church combined with an emphasis that all sins be confessed would lead to an unequal fixation on sin and guilt.

Within these two differing bodies of Christian philosophy, many questions have been raised relating to feelings of culpability as manifested in guilt. Although there is not a precise definition of guilt, self reproach, self punishment and remorse seem to be a central theme.

These two religious philosophies offer extensive avenues for contemplation, be it autonomous thought or deeply rooted ritual.

A comparative analysis of Protestant and Catholic guilt association has yet to be done. As has been discussed, adherence to the Catholic faith allows many instances of guilt preoccupation, therefore it is proposed that adherence to the Catholic faith will result in higher guilt than adherence to the Lutheran faith. Further predicted is that overall Catholics will have higher guilt scores than Lutherans, and higher religiosity with either faith will result in more guilt.

METHOD

Subjects

Subjects in the study were male and female students enrolled in classes at a Liberal Arts College in the upper midwest. Information was requested voluntarily from three introductory psychology classes, a third level psychology class, and a third level religion class to ensure a large sample size. There were 58 students given the opportunity to participate voluntarily in this study. Their ages ranged from 19 to 28.

Apparatus

Subjects were asked to answer survey questions to measure guilt association with the Situational Guilt Scale (Klass 1983, 1987). Attitude toward the value of and acceptance of a religious way of life were measured using The Religion Scale (Bardis, 1961). In addition, subjects were asked what religious background they were brought up in. Those specific subjects who indicated Lutheran or Catholic were used in the comparative study.

The Situational Guilt Scale, or (SGS) is a self reported survey that measures the degree of anticipated guilt feelings for a wide range of naturally occurring stimulus situations (Klass 1983, 1987). Subjects are presented with 22 separate situations and are asked to imagine themselves in that particular situation. Then they indicate the intensity of their emotional reaction on four dimensions (regret, self-disappointment, guilt, and shame) using a 1 to 5 Likert scale. Higher scores indicate higher guilt. The measure yields a Total Guilt Score and several subscale scores including Interpersonal Harm Guilt, Norm Violation Guilt, and Self-Control Failure Guilt (Klass 1983, 1987). The (SGS) reported a Cronbach Alpha coefficient of .92 and a test-retest reliability of .90 for Total Guilt as well as acceptable construct, convergent, and discriminant validity (Klass-1983, 1987).

The Religion Scale is a 25-item, Likert type scale developed to measure positivity of attitude toward religious faith and other religious referents (Bardis, 1961). The measure reports a split-half reliability of .90, based upon an N of 130. The items were selected to discriminate between high and low scorers, high scores indicate positive attitudes toward religion. This scale has test-retest reliabilities of .94 and .84 based on samples of 52 subjects.

Scales were piloted on nine people to examine for time duration and problems including clarity, clerical errors, misinterpretations, ambiguity, and bias. Only one problem was identified. The Religion Scale (Bardis, 1961) lacked negatively phrased items. Accordingly, three items were reversed to discourage response sets. Confederates needed twenty minutes to complete surveys.

Analysis

Subjects were split out on the basis of their indication of Lutheran or Catholic background. The Situational Guilt Scale (Klass 1983, 1987) yields a total range of scores from 22 to 110 on each of the four dimensions (regret, self-disappointment, guilt, and shame). A t-test was used to determine significance between the Catholic and Lutheran mean scores on Total Guilt.

The Religion Scale has a total range of scores from 0 to 100. A comparison of correlation was used to determine adherence and explore the relationship between Catholic and Lutheran scores on Total Guilt. In this analysis, guilt scores were correlated with religious adherence for each of the two groups.

The last comparison involved differentiating between the two significant observed values of "r" for the Catholic group and the Lutheran group. If the observed value of "r" for the Catholic group was not significantly different from the observed value of "r" for the Lutheran group, I would not have support for my hypothesis that adherence to the Catholic faith would result in higher guilt than adherence to the Lutheran faith, and I would fail to reject the null and reason that these groups were similar distributions in the population.

RESULTS

Individual survey questions were intercorrelated to determine their reliability in measuring guilt and religiosity in the subjects I surveyed. Item intercorrelations were done for each scale to determine if specific questions were well designed for this study. Three questions were thrown out of each survey because they did not correlate significantly with the rest of the questions in the scales, $p > .05$. On the Situational Guilt Scale (Klass 1983, 1987), survey questions 2, 10, and 14 were omitted, and on The Religion Scale (Bardis, 1961), survey questions 9, 22, and 23 were dropped.

Survey information was compiled from five different classes to attain the representative sample. An analysis was done to compare the diverse data for congruity. T-tests for data relating to individual classes affirmed their similarity for combining.

Table 1

Comparison of Means and Standard Deviations by Class
t-tests for Independent Samples on guilt

	Catholic			*Lutheran*		
	N	Mean	Standard Deviation	N	Mean	Standard Deviation
Class one	(3)	64.67	16.56	(6)	70.17	12.34
Class two	(5)	67.30	11.00	(7)	68.43	12.21
Class three	(5)	58.60	19.01	(2)	61.00	15.56
Class four	(5)	59.80	23.66	(5)	61.40	25.24
Class five	(0)	-----	-----	(1)	71.00	-----
Overall	(18)	62.36	17.08	(21)	66.67	15.43

(across classes)

An analysis for a difference in guilt between means of Catholics and Lutherans was done with a t-test. Significance was not established, $t = -.83$, $p = .41$. With the Catholic mean at 62.4 and the Lutheran mean at 66.7, the trend appeared to be in the wrong direction from what I predicted.

A correlation for the relationship between religiosity and guilt was done for Catholics and Lutherans. In partial support for my hypothesis, significance was found for Lutherans, $r = .58$, $p = .006$, indicating higher religiosity scores correlated with higher guilt scores for Lutherans. Significance was not found for Catholics in this sample, $r = -.12$, $p = .63$.

The last comparison was not performed to determine if adherence to the Catholic faith would result in higher guilt than adherence to the Lutheran faith, because
there were not two significant correlations to differentiate between.

DISCUSSION

I reasoned that in light of particular instances of guilt preoccupation in the Catholic faith, adherence to the Catholic faith would result in higher guilt than adherence to the Lutheran faith. I could not provide credible empirical support for this prediction in the analysis of this data. In this sample, I did not find significance within the Catholic scores
on religious adherence relating to higher guilt to find support for higher guilt adherent Catholics in comparison to higher guilt adherent Lutherans. I believe I did not find support for the assumption that adherence to the Catholic faith would result in more guilt than adherence to the Lutheran faith because of the limited range of Catholic adherence in this study.

I further anticipated that Catholics would have higher guilt scores than Lutherans with an analysis of means between Lutherans and Catholics. Although without significance at $p > .05$, I found that Catholics did not have higher guilt scores in my study than Lutherans, rather they appeared about the same. Again I believe I did not find support for this assumption because of the limited range of Catholic adherence in this study.

Table 2

Descriptive Statistics for Catholics and Lutherans on Religious Adherence (range 0-88)

	Catholic	*Lutheran*
Mean	40.39	53.12
Standard Deviation	18.22	15.94
Minimum	10.00	18.00
Maximum	67.00	80.00
N	18	21

I additionally predicted that higher religiosity would result in higher guilt for both religions. Higher religiosity did correlate with higher guilt for Lutherans, but I did not find support for Catholics. I actually found, although insignificantly, contrasting patterns in this data suggesting a difference in adherence patterns between Lutherans and Catholics.

The data for this study came from one source, a private Lutheran college. The sample included a good number of adherent Lutherans, but unfortunately adherent Catholics were relatively underrepresented in this study.

To continue this study I would like to find a more diverse sample in which a range of adherence for Lutherans and Catholics conceivably would be included. I could make use of a public university where a more diverse sample could possibly be found and repeat the study, or give the Situational Guilt Scale (Klass 1983, 1987) and the Religion Scale (Bardis, 1961) to a private Catholic college, similar in characteristics to the college this sample was drawn from, and compare the additional data.

Future directions to build on would be age as an additional variable. Different stages of growth affect religious adherence. Young people tend to positively accept their parents' religious views unquestionably at an early age. On the other hand, adolescence appears to be a time for individual personhood and development of personal autonomy when peers may become more important and parents less influential. Do patterns of adherence vary between these two religious backgrounds, and if so is age the determining variable? Similarly, college adjustment involves diminished parental influence and increased peer influence. Could a pattern of diminished adherence between these two religions result in varying instances of guilt? Therefore college adjustment could also be tapped into as an additional factor in assessing guilt between these two religious backgrounds.

Locus of Control and Superstitious Behavior: A Visit to the Putting Green

Mark W. Jones

Department of Psychology
Hendrix College
1600 Washington Avenue
Conway, AR 72032

Faculty Advisor:

Ralph J. McKenna

Forty-two college students were required to successfully sink six five-foot putts on an indoor, astro-turf covered plywood putting green. Prior to each attempt, students chose one of five different colored balls from a bucket. The color of the balls used for each successful putt and for the subsequent attempted putt were recorded. Superstitious behavior was defined as choice of the same color ball following a successful putt. Based upon similar research focusing on chance orientation (Van Raalte et al., 1991) it was predicted that individuals internal in locus of control (Rotter, 1966) would be more likely to exhibit superstitious behavior. Directional support for the hypothesis was found. Alternative interpretations of the data are considered, based upon superstitious avoidance of balls following missed putts.

BACKGROUND

The employment of superstitious behavior is a common practice across a variety of cultures. In ançient times, individuals were sacrificed to appease the gods. This ritualistic act was deemed necessary in order to increase chances of survival. While today's society has abandoned the ritualistic act of human sacrifice, many less extreme forms of superstitious behavior still exist. Many people are afraid to walk under a ladder or to have a black cat cross their paths. Athletes employ a number of rituals to "enhance" their performances. However, it is difficult to point to specific reasons for believing in the efficacy of superstitious behavior.

A number of factors can be taken into account when investigating superstitions. One possible factor is locus of control. Individuals who are internal in locus of control believe they possess the abilities and skills to influence their surroundings. People who are external in locus of control attribute situational occurrences to chance, luck, or some factor outside of their control. The extent to which an individual believes to control one's life could influence whether or not the person practices superstitious behavior.

Superstitious behavior also can serve as positive reinforcement by allowing individuals to function better. Several previous studies have examined superstitious behavior. Wyrostok (1995) examined the use of rituals as a form of therapy to help individuals cope with grief and anxiety. Becker (1975) found that athletes who use superstitious behavior have a greater sense of confidence and control in a sporting event. Neil (1980) also researched the use of rituals among athletes and found that superstitious behavior lowered anxiety and helped athletes manage stressful situations. The use of rituals as a therapeutic device can help individuals gain a sense of control and reduce feelings of anxiety.

Additional studies have explored the downfalls associated with superstitious behavior. Tobacyk and Shrader (1991) found that individuals measuring high in superstitious beliefs also had low self-efficacy scores. Berman (1991) found that many people have rituals against boasting because these individuals are afraid to tempt fate. White and Liu (1995) examined the behaviorist view on superstition and found that a superstitious response can be reinforced and maintained by associating superstitious behavior with inappropriate events. Individuals can be misled into thinking their rituals influence events occurring in another place.

Locus of control also has been examined in several previous studies. Burger (1991) found that lottery players measuring high in desire for control were more likely to choose their own lotto numbers than have a machine select their numbers. Matute (1994) conducted an experiment to examine learned helplessness in participants when exposed to uncontrollable noise. While Matute expected to observe learned helplessness in an uncontrollable situation, participants employed superstitious behaviors and illusion-of-control effects. Superstitious behaviors allowed the participants to believe they had control in the situation.

The relationship between chance orientation and superstitious behavior was examined by Van Raalte, Brewer, Nemeroff, and Linder (1991). Individuals who are low in chance orientation are similar to people who are internal in locus of control. Low chance orientation individuals believe their actions can influence outcomes. However, individuals who are high in chance orientation, much like people who are external in locus of control, believe that events in life are beyond their control.

Van Raalte et al. (1991) found that participants low in chance orientation were more likely to practice superstitious behavior than individuals high in chance orientation. Participants who believed they could control chance events attributed a successful golf putt to a lucky ball, an example of superstitious behavior. The Van Raalte et al. study further confirms that a positive correlation exists between the perceived ability to control events and the use of superstitious behaviors.

The purpose of this study was to examine the relationship between locus of control and superstitious behavior. When performing in an activity, individuals who are internal in locus of control would be more likely to believe they can influence the outcome of the activity. In order for internally controlled individuals to perform with greater confidence and control, these individuals may use superstitious behavior. However, people who are external in locus of control would believe that their fate is already determined when they are asked to participate in an event. Therefore, these individuals would have no use for superstitious behaviors that could possibly reduce feelings related to a lack of control.

The independent variable in this study was a participant's measure in locus of control. The dependent variable was the measure of superstitious behavior the participant employed in a golf ball putting activity. Superstitious behavior constituted the use of the same color ball following a successful putt. It was predicted that individuals internal in locus of control would be more likely to exhibit superstitious behavior than individuals external in locus of control.

METHOD

Participants

Forty-two Hendrix College General Psychology students (24 women and 18 men, mean age = 19.1 years) participated in the study. Participants volunteered to take part in the study, and the participants signed up in groups of two. Each individual received bonus points in exchange for participation.

Materials

An astro-turf covered plywood sheet measuring 4 feet in width and 8 feet in length served as the putting area. The hole or "cup" was positioned 5 feet away from the area where participants stood when attempting a putt. Two 12-inch bricks also were wrapped in astro-turf and placed in a "V-shaped" position behind the hole. The bricks served as deflectors and helped to make the task less difficult. Participants could make the balls deflect off the bricks and into the hole or putt the ball directly into the hole to complete a successful putt. A two-way putter was used as the golf club so that both left-handed and right-handed participants were able to attempt the putts. Golf ball colors were red, yellow, blue, silver, and brown. The brand labels on all of the balls were covered, and a ball's color was the only way to distinguish one ball from another ball. A total of 30 balls, 5 of each color, and 6 small buckets also were required. At the conclusion of the putting task, participants answered demographic questions, completed the Rotter Internal - External Scale (Rotter, 1966), and filled out a post-experiment reaction inventory. Demographic information included gender, age, and classification. The post-experiment reaction inventory served as a

814

manipulation check, and it allowed the participants to express their views about the study. Participant numbers appeared on all pages of the questionnaire packet.

Rotter Internal - External Control Scale. Rotter (1966) constructed this scale to measure locus of control. This inventory consisted of 29 forced-choice items. Six of the items were filler items, and scores could range from a high of 23 to a low of 0. A high score indicated that an individual was external in locus of control, and a low score predicted that an individual was internal in locus of control. This inventory has a test-retest correlation between .49 and .83 and an internal consistency rating from .65 to .79.

Procedure

Participants reported to the designated research site in groups of two. Six participants took part in the study each hour. When participants arrived at the research location, they were greeted by the experimenter. The experimenter told participants that they were going to take part in a study designed to measure hand-eye coordination. This explanation was necessary to serve as incentive for participants to perform as well as possible on the task. Participants putted until they had sunk 6 successful putts. Each successful putt had to be made using a ball from each of the 6 buckets.

The experimenter stood near the hole. After each putting attempt, the experimenter recorded the color of the ball and if the putt was or was not successful. Following a successful attempt, the experimenter allowed the participant to choose a ball from the next bucket of balls. After an unsuccessful attempt, the experimenter placed the missed ball back into its original bucket. The participant then chose any ball to putt from the same bucket. This process continued until each participant had made 6 successful putts with a ball from each bucket. Superstitious behavior was considered if the participant selected the same color ball following a successful putt more frequently than chance selection would suggest. Superstitious behavior scores could range from a low of 0 to a high of 5, and each participant was assigned a superstitious behavior score based upon this 6-point Likert scale.

After each participant completed the putting task, the experimenter explained to the participant that his or her hand-eye coordination was normal. Then, each participant was instructed to complete the questionnaire packet. A full debriefing occurred at a later date after all participants completed the experiment. The experimenter addressed the entire group of participants and explained the purpose of the study and answered questions.

RESULTS

The primary mode of analysis involved independent t tests, and an alpha level of .05 was used to assess statistical significance in all analyses. The hypothesis received directional support, but no statistical significance was evident in any analysis.

Participants were divided into an internal or external group according to their locus of control scores. Scores higher than 11 were counted as external, and scores of 11 and below were recorded as internal. Superstitious behavior scores were matched with the corresponding participant in either the external or internal group. Table 1 includes the mean superstitious behavior scores for participants who were external and internal in locus of control. The difference between superstitious behavior scores for externals and internals was not significant, t (34) = .25, p = .80. Directional support for the hypothesis was evident.

Table 1: Mean Superstitious Behavior Scores and Locus of Control

Locus of Control	Superstitious Behavior
Internal	1.50 (1.29)
External	1.39 (1.46)

Note. Numbers in parentheses represent standard deviations. Data consist of scores obtained from all 42 participants.

In order to more adequately assess locus of control, participants whose locus of control scores ranged from 8 to 15 were eliminated, and separate t tests were performed. Table 2 illustrates the mean superstitious behavior scores for 12 participants who scored most external and 12 participants who scored most internal. The difference between superstitious behavior scores for these externals and internals approached marginal significance, $t(22) = 1.65$, $p = .11$. Directional support for the hypothesis was revealed.

Table 2. Mean Superstitious Behavior Scores and Most Extreme Locus of Control

Locus of Control	Superstitious Behavior
Internal	2.08 (1.38)
External	1.17 (1.34)

Note. Numbers in parentheses represent standard deviations. Data consist of scores obtained from highest 12 locus of control scores (external) and lowest 12 locus of control scores (internal).

At the conclusion of the study, a different type of superstitious behavior was examined. This type of superstitious behavior involved avoidance of the same color ball following an unsuccessful putt. A chi square comparison with the basic two cell design containing locus of control (internal and external) and same color after an unsuccessful putt (yes and no) was conducted. Locus of control scores were used for 12 participants with highest external scores and 12 participants with the highest internal scores. Table 3 illustrates the relationship between locus of control and superstitious avoidance behavior. Externals displayed greater avoidance superstitious behavior, $\chi^2(1, N = 39) = 3.12$, $p = .08$.

Table 3. Superstitious Avoidance Behavior and Locus of Control

Avoidance Behavior	Internal	External
Yes	17 (19.23)	13 (10.77)
No	8 (5.77)	1 (3.23)

Note. Numbers in parentheses represent expected frequencies. "Yes" in avoidance behavior indicates a participant avoided balls following missed putts, and "No" in avoidance behavior indicates a participant did not avoid balls following missed putts.

Results from this study also indicate no gender difference in superstitious behavior or locus control. Males and females appear to measure similarly in both superstitious behavior and locus of control.

DISCUSSION

The results indicate both directional support and rejection for the hypothesis. When superstitious behavior is defined as choice of the same color ball following a successful putt, directional support is provided for the hypothesis. However, if superstitious behavior is defined as the avoidance of the same color ball following an unsuccessful putt, the hypothesis is rejected.

The initial means of measuring superstitious behavior was a participant's selection of the same color ball after a successful putt. When superstitious behavior is defined in this manner, internally controlled individuals demonstrate more superstitious beliefs than externally controlled individuals.

This relationship between locus of control and superstitious behavior is evident to a greater extent when an individual is highly internal or highly external. When locus of control scores clearly place an individual into the internal or external category, internals appear to be much more superstitious than externals. This finding provides support for the Van Raalte et al. (1991) study, which defined superstitious behavior in a similar fashion. Both the Van Raalte et al. finding and the results obtained in this study provide evidence that internals practice more superstitious beliefs than externals when superstitious behavior involves maintaining good luck.

However, when superstitious behavior is based upon the avoidance of balls following unsuccessful putts, results indicate an alternative explanation for the relationship between locus of control and superstitious behavior. This study has indicated that externals are much more superstitious than internals when superstitious behavior involves avoiding bad luck.

The Van Raalte et al. (1991) study did not mention any results pertaining to superstitious avoidance behavior. Therefore, this study may be the first to assess locus of control and type of superstitious behavior employed by individuals. Internals appear to be more superstitious in a situation where the maintenance of good luck is desirable, and externals seem to be more superstitious in a situation where the avoidance of bad luck is beneficial. However, more research is necessary to support this finding on locus of control and superstitious behavior.

Potential problems in this study also may have contributed to confounded results. The 5 golf balls did not lie evenly at the bottom of each bucket. One ball was positioned higher than the others, and the participants may have selected the top ball because it was at the top of the bucket. However, a participant's fondness or dislike for a particular color should have allowed this individual to choose a ball located at any position in the bucket.

Another potential problem could involve the participant's knowledge about the study. If a participant knew the underlying purpose of the study, this individual's data could have skewed the results. However, the post-experiment reaction inventories revealed that the majority of the participants who believed something more than hand-eye coordination was being measured did not believe superstitious behavior was involved. Many participants thought perseverance was being assessed. Therefore, a participant's knowledge about the study can be eliminated as a possible problem.

This study provides evidence of some type of relationship between superstitious behavior and locus of control. However, more research between these concepts is necessary in order to make a valid statement as to the exact nature of the relationship between superstitious beliefs and locus of control.

Excessive eating is considered to be the primary factor that contributes to weight gain in many organisms. We assume that the more food that is presented to an animal, the more the animal will eat, and the heavier the animal will become. The current study investigated the effects of *ad lib.* feeding for 14 months on weight and health of 48 Long-Evans hooded rats raised under different handling and grouping conditions. The results indicated that long-term *ad lib.* feeding resulted in excessive weight gain in male subjects but not in female subjects, regardless of rearing conditions. Results suggested that the fitness of laboratory animals may be compromised when animals are fed on a free-feeding basis.

INTRODUCTION

Laboratory rats serve as subjects for a wide variety of behavioral studies. In this role as experimental subjects, rats are frequently tickled, scratched, petted, carried to and fro, and handled extensively during the course of an experiment. Such handling may sometimes have profound and unanticipated effects on the subject (Davis & Perusse, 1988). Researchers are aware that maintaining a high level of health in their laboratory animals is essential for acquiring valid data during experimental manipulations. Both the rate of development that is present early in the animal's life and the total weight of the animal throughout its life are considered good measures used to assess the health of the laboratory rats. However beyond the first 4 months of life for laboratory rats, limited growth data have been published (e.g. Charles Rivers Laboratory (CRL), 1997; Poiley, 1972).

The growth of animals, both functionally and structurally, is determined partly by genetics and partly by environment (Roubicek & Ray, 1971). Past research suggests that weight gain in rats may be affected by the conditions under which it is raised (Bernstein, 1952; McClelland, 1956; Denenberg & Karas, 1959; Ruegamer, Bernstein, & Benjamen, 1954; Sobel, Zuppinger, & Joss, 1979). Weininger, McClelland, & Arima (1954) stated that rats that were "gentled" by being held and stroked for a few minutes each day increased their rate of growth compared to those not gentled. Other investigators found that gentled animals showed a significant increase in body weight and skeletal length over non-gentled animals (Winokur, Stern, & Taylor, 1959). King (1969) reported no differences between handled and nonhandled rats. The reason for the possible effect of handling on growth is not known; however, metabolic or stress related factors may be involved (Ruegamer et al., 1954).

Another factor that may influence the weight gain of laboratory rats is the housing conditions in which the animals are raised. Weininger et al. (1954) reported that albino mice housed in group cages were heavier than mice

818

individually housed. They found that mice isolated in separate cages failed to grow as fast as those that were grouped two, four, or six in a cage. On the other hand, Fiala, Snow, & Greenough (1976), reported that isolated animals weighed more than grouped housed animals and suggested that the isolated animals may simply eat more to relieve the boredom of their situation.

Therefore, the purpose of the present study was to acquire growth data on laboratory rats over an extended period of time and to evaluate the effects of *ad lib.* feeding and environmental manipulations on the weight gain of male and female rats. In addition, we were interested in documenting weight gain over a long period of time. This study extends the findings of Lawrence, Doraiswami, & Stahl (1996), which reported the first 6 months of growth data from these animals.

METHOD

Subjects

Subjects were 48 Long-Evans hooded rats who were offspring of one of five timed-pregnant rats obtained from the Charles Rivers Laboratory (Portage, MI). They were studied from 21 to 441 days of age.

Materials

Food (Purina rodent pellets #5001), water, poly-carbonated cages, sawdust, and a weighing scale were the only materials required for this project. The animals were housed in an animal facility with a 12/12 light/dark cycle.

Procedures

Litter Consolidation. On the day after birth, pups were separated from their mothers and redistributed using a modified split-litter design. Litters were consolidated on day 1 so that each of the 4 mothers had 12 pups (6 male and 6 female). At the age of 14 days, dry food chow was placed inside of each cage to get the pups used to solid food.

Separation. On day 21, pups were separated from their mother (or foster mother), placed in poly-carbonated cages, and housed either individually or in same sex triads. Animals in group cages received ear clips for identification purposes.

Handling and Weighing. All animals were weighed every 3 days for 14 months. Twenty-four animals were handled every day for 4 weeks immediately after separation from their mother. The animals that were handled included 12 males and 12 females. Of the 24 animals in each handling condition, 12 were grouped into 4 groups of 3 rats, and the remainder were individually caged. Handling consisted of picking the subject up by the base of its tail or its body and holding it in the left hand. The experimenter's left arm was placed against his or her chest, so that the subject was secure, and the rat was stroked gently with the right thumb for 5 minutes continuously from the rat's head to the base of its tail. All handling and weighing took place during the middle of the light cycle. At 411 days of age, the group-housed individuals were separated and individually housed for the last stage of the study in which food intake was measured and then animals were transferred to a veterinary facility for necropsy and health assessment.

RESULTS

The results for male rats indicated that a combination of handling and environmental enrichment (group caging) resulted in the highest amount of weight gain while the combination of handling and non-enriched environment (single caging) resulted in the lowest amount of weight gain (shown in Figure 1). There was also a small difference in the weight gain between male group-caged and handled rats and male single-caged and handled rats. Differences are not significant with the exception of male grouped handled rats, and this may be compromised by litter effect; all males from the lowest weight litter happened to be assigned to the two low-weight handling and grouping conditions.

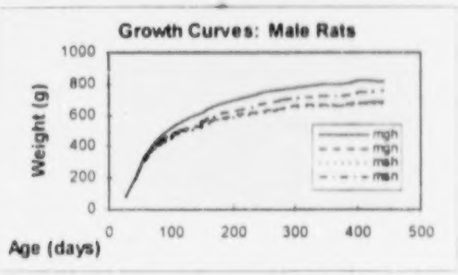

Figure 1. Growth curves for male rats in different rearing groups. In the legend titles, "m" = male, "g" = grouped housed, "s" = single housed, "h" = handled, and "n" = non-handled.

The results for female rats indicated that the single-caged handled rats weighed more than the other animals. In contrast to the findings with the male rats, the results for female rats (shown in Figure 2) indicated that the group-caged non-handled rats and single-caged handled rats had identical weights and demonstrated the highest weight gain while single-caged non-handled rats had the lowest weight gain. Surprisingly, there were no significant difference among the female rats.

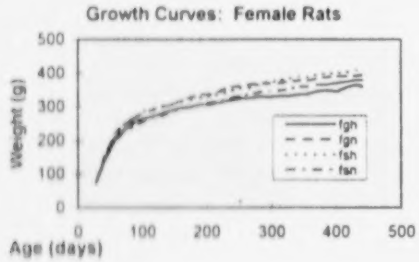

Figure 2. Growth curves for female rats in different rearing groups. In the legend titles, "f" = female, "g" = grouped housed, "s" = single housed, "h" = handled, and "n" = non-handled.

Other Health Related Findings. Although animals in our groups did not differ from one another, male rats gained more weight faster than those raised under comparable conditions at other facilities (CRL, 1997). As a result, the males as a group were quite obese by the end of the study. Necropsy revealed excessive adipose tissue in nearly all male subjects.

Females, on the other hand, maintained a rate of growth similar to that published by the animal supplier (CRL), although they developed more tumors and other related problems than did their male counterparts (see Table 1). One tumor was 8x8 cm and weighed 113g, severely impairing this individual's mobility. Beyond these findings, the rats exhibited no unusual pathology.

Examination of food consumption per unit body weight revealed that, at the end of the study, females ate significantly more food than males (5.0% vs 3.8% of body wt. daily; $F = 94.76$, $df = 1$, $p < .05$), indicating metabolic differences between the sexes at this time.

Table 1. Pathology report for selected rats.

Rat ID	Sex	Weight 1/7/97	Veterinary pathology report
1332	F	456 g	113 g mammary fibroandenoma
1334	F	389 g	streptococcal skin abscesses
1344	F	412 g	unidentified yellow nodules, excessive adipose tissue
1346	F	325 g	mild mammary gland cysts
1349	M	838 g	nephropathy, excessive adipose tissue
1351	M	940 g	nephropathy, excessive adipose tissue (largest male)
1355	F	326 g	nephropathy
1356	F	459 g	alopecia (hair loss)
1357	F	415 g	nephropathy
1358	F	488 g	excessive adipose tissue (largest female)
1362	M	746 g	excessive adipose tissue
1367	F	326 g	excessive adipose tissue
1369	F	330 g	nephropathy
1370	F	377 g	excessive adipose tissue

DISCUSSION

Handling and grouping, as we did there, did not have a significant impact on the growth rate of the animals; several rats appeared to be robust. The most impressive result of the study was that *ad lib* feeding, carried out over an extended period of time (14 months), resulted in extreme obesity in nearly all male rats, but not female rats. Whether the metabolic differences found at the end of the study were cause or effect of obesity, obesity is not known and will require further study. The results to date demonstrate that the health of laboratory animals is compromised when animals are fed on a free-feeding basis and suggest that researchers should control the daily diet of experimental subjects.

Drug State Dependent Performance of Rats on a Hampton Court Maze

Shawana N. Lewis and Gary L. Lawrence

State dependent learning (SDL), or dissociated, is demonstrated when information learned in one chemical state fails to transfer or only partially transfers when an organism is tested in a different chemical state. In the present study 12 naive male Long-Evans hooded rats learned the Hampton Court Maze under the influence of saline or one of various doses of morphine and then were tested in the other chemical condition. Results provided evidence of state dependent learning only at 15 mg/kg doses of morphine and saline. Most subjects demonstrated significant increases in the time it took to run the maze when changed either from the saline to morphine state or from the morphine to the saline condition.

BACKGROUND

State dependent learning (SDL), or dissociation, is exhibited when behavioral responses learned while an animal is under the influence of a centrally acting drug are performed most efficiently only when the same drug condition is reestablished (Combe, 1835, Overton, 1984). Research suggests that memory retrieval is impaired during tests performed without the drug or when the animal is under the influence of drugs different than the original drug and that the degree of the effect is usually related to the drug dose (Barry, 1974). Girden and Culler (1937) reported the first experimental demonstration of SDL while investigating the ability of dogs to acquire a conditioned leg flexion responses when paralyzed with curare. They noted that not only could such responses be learned, but that their subsequent performance was state dependent. More recently, Stahl and Pieper (1989) found evidence of SDL when they investigated the performance of rats on the Maier Three-Table Reasoning Problem. They found that rats that were given saline, morphine, or methadone for the two experiences and the test performed well on the task. However, rats given the two experiences in different drug states performed poorly.

In the past, the SDL phenomenon was tested using tasks that could be quickly learned by the rat such as step-through tasks, runway mazes, and T-mazes (Overton, 1974, 1991, Nishimura, Shiigi, & Kancto, 1990). Because these tasks are quickly learned and relearned, they may not be as sensitive to state-dependent changes in learning as a more complex task that entails an extended learning curve; therefore, we chose Small's Hampton Court Maze (Small, 1901). In Small's words, the Hampton course maze was developed to make observations upon the "free expression of the animal's mental processes, under as definitely controlled conditions as possible, and at the same time, to minimize the inhibitive influences of restraint, confinement and unfamiliar or unnatural circumstances (Small, 1901, p. 93)." Although many textbooks make reference to the Hampton Court Maze, very few experiments have been published using the maze. Furthermore, literature suggests that there are several unsolved problems with experimental design and methodology when it comes to state-dependent learning studies (Overton, 1974). Other plausible conclusions include significant behavioral effects, other than SDL, that can be produced by the drugs. Drug-induced SDL has not been investigated at length since about 1980 when it was concluded that the doses of psychoactive drugs normally used for outpatient treatment do not produce the phenomenon to an convincing degree (Eich, 1980, Lowe, 1982). Therefore, the present study was designed to expand upon past SDL studies by using the Hampton Court Maze, a task that is more difficult for the subject to learn.

METHOD

Subjects

Twelve experimentally-naive male Long-Evans hooded rats obtained from the Charles Rivers Laboratories (Portage, MI) served as subjects for this study. They were 94-107 days old and weighed between 309 to 349 gm at the start of the testing. The subjects were fed sufficient Laboratory Rodent Diet (#5110, PMI Feeds, Inc.) to maintain their weights at 85% of their *ad lib.* weights and were given water *ad lib.*

Apparatus

The Small (1901) Hampton Court Maze was modified for use in this study by placing a block at the one point at which Small's maze provided two correct paths to the goal. The maze, shown in Figure 1, had one correct route, requiring 42 turns and 7 decision points to reach the central goal box. The maze was 150cm long, 100cm wide, and 15cm tall, constructed of 1cm thick Thermasheth, making the apparatus lightweight to facilitate cleaning between subjects. Alleyways were 7cm wide, the central goal box was 25cm wide by 30cm long, and surfaces visible to the animal were painted flat black.

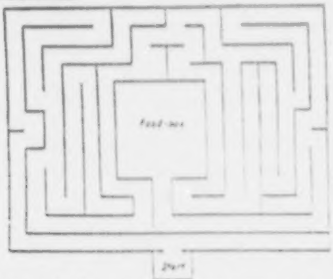

Figure 1. Revised Hampton Court Maze

Procedures

Handling and Adaptation. For five days prior to their first run of the maze route, subjects were familiarized with both the experimenter and the maze. The first 2 days each animal was handled and petted for 5 minutes each day. On the final 3 days, animals were carried to the test room in groups of 4, handled for 5 minutes, and then placed at the entrance of the maze. They were allowed to explore the entire apparatus for 30 minutes. The amounts of time that each animal urinated, defecated, squealed, and the percentage of the maze that each animal explored was recorded. No food was available during the adaptation period.

Drug Administration. Prior to the start of the maze-running sessions, each subject was given a 1ml injection of saline or morphine sulfate at doses of 6 , 10, and 15 mg per kg body weight. The subject was then placed in a holding box for 30 minutes before being put in the maze by a second experimenter for the first trial of the day. The animal tester did not know the dose of morphine or saline (0, 6, 10, or 15 mg/kg) that the animal had received.

The study functioned under an ABA design, with some subjects initially learning the maze after being injected with saline and others after receiving a dose of morphine. The criteria performance to change chemical conditions was defined as three consecutive days (15 trials) completing the maze with a stable running time (under 30 seconds) and no more than one error. After this level of performance was achieved, the injection experimenter switched the subject to another dosage level that was unknown to the animal tester.

Maze-Running Trials. Upon removal from the holding box, each subject was carried to the goal box of the maze and allowed to eat for 30 seconds. It was then retrieved from the goal box and placed in the start box. After 30 seconds had passed and the animal was facing the door, the experimenter lifted the door giving the rat access to the maze paths. If after 1 minute the animal had not left the start box, it was coached out of the box and the door was closed behind it. The animal was then given 5 minutes to reach the food in the goal box. The animal was given 5 sequential trials per day, five days per week. The amount of time it took the animal to reach the goal box, up to a maximum of 5 minutes, constituted a trial. If the animal did not reach the goal box within 5 minutes, it was retrieved from the maze, replaced in the start box, and the next trial began. At the end of the fifth trial, the animal was returned to its home cage and fed. Each animal was tested individually and at the same time each day. After each animal completed testing, the paper under the maze was removed and the floor was mopped.

Data Recording. As each subject ran the maze, the animal tester traced its route on a 4 ½ by 6 inch photocopied representation of the maze. Incorrect turns and paths that were retraced (errors) were marked with an "X" and then totaled at the end of the trial. The experimenters also noted (in seconds) latency to leave the start box once the door had been opened and running time from the start box to the goal box.

BEST COPY AVAILABLE

RESULTS

After completion of the experiment, data representing drug dose, latency, running time, and errors for each trial were analyzed using SPSS for Windows. Descriptive analysis consisted of within-subject comparisons of performance before and after dose changes as well as between-group comparisons of animals who were in the different ABA conditions. The results demonstrated no evidence of state dependent learning at low doses; subjects tested on 6 mg/kg doses performed similarly on drugged and nondrugged states. However, at 15 mg/kg doses, the subjects demonstrated increases in the time it took to run the maze when changed either from the saline to morphine state or from the morphine to the saline condition (Figure 2). Their running times increased from an average of 18.6 seconds to an average of 73.2 seconds to complete the maze.

As shown in Figure 3, the average amount of time it took the subjects to learn the maze and complete it with the minimal amount of errors was about 14 days regardless of the drug condition under which that initial learning occurred. In addition, re-learning the maze after the initial state change took four to five days, which was more than the minimum amount of days required to meet criteria. Figures 4a, 4b, and 4c depict individual cases that contributed to these results.

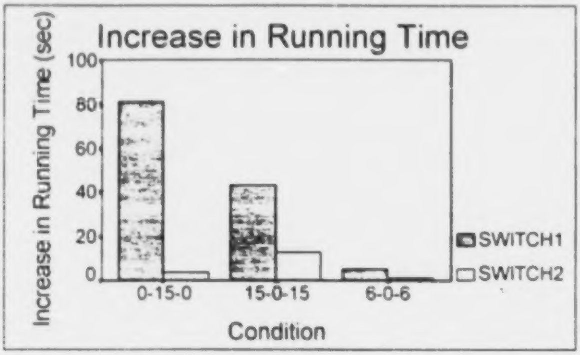

Figure 2. SWITCH 1 reflects average running time after the first condition change, SWITCH 2 reflects average running time after the second condition change. In Figure 2 and Figure 3, 0-15-0 indicates that animals were switched from saline to morphine to saline, 15-0-15 indicates that the animals were switched from morphine to saline to morphine, and 6-0-6 indicates that the animals were switched from a lower dose for morphine to saline to morphine.

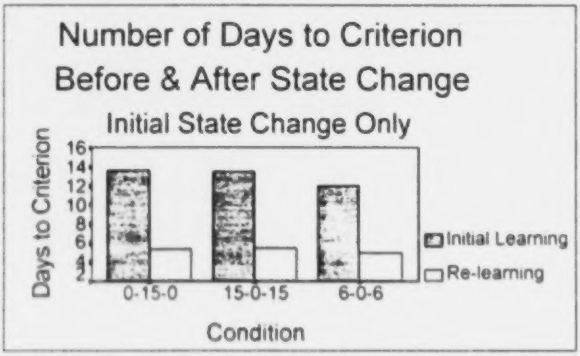

Figure 3. Initial Learning refers to the average number of days for subjects to perform to criteria before the initial state change. Re-learning refers to the average number of days for subjects to perform to criteria after the initial state change.

Figure 4a

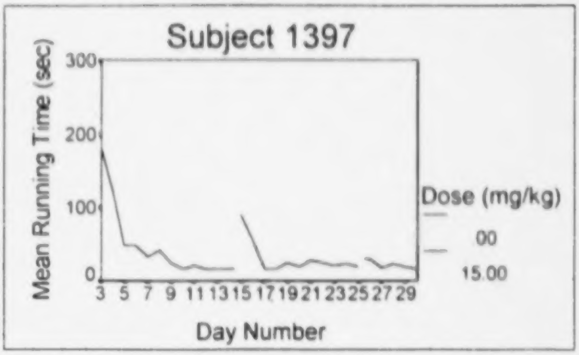

Figure 4b

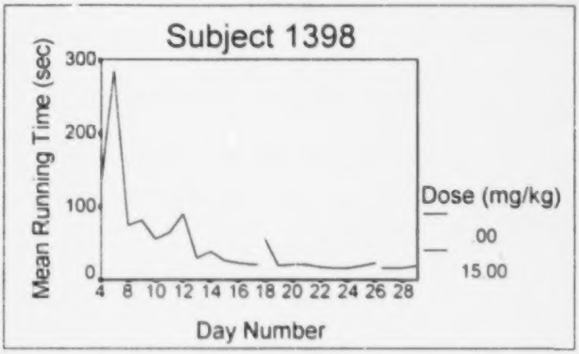

Figure 4c

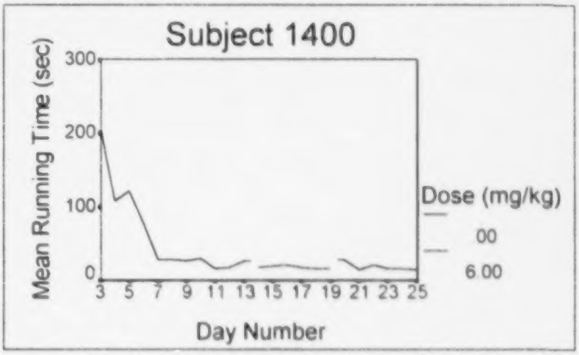

Figure 4a-4c. Figures reflect only the days in which subjects completed the maze.

DISCUSSION

The findings in the current study supported our hypothesis that the subjects' performances would suggest state-dependent learning. The increases in running time for subjects on high doses (15 mg/kg) were concluded to be the effect of state-dependent learning rather than more generalized drug effects because the change was just as significant going from morphine to saline as it was going from saline to morphine In addition, state-dependent learning appeared to be evident in that the subjects' running times and days to criterial performance after the second switch were considerably less than they were during initial learning and after the first switch However, the results did not support our hypothesis for subjects that were given low doses (6 mg/kg) which suggests that 6 mg/kg is not discriminable from saline

Twelve subjects have been tested in the first experiment We do not consider our findings to be conclusive until we test an addition 12 subjects with additional doses of the drug Future research can be done to make some detailed analysis so as to understand more about the role of neurotransmitter systems in specific processes involved in learning and/or retrieval

Child Abandonment in St. Petersburg, Russia: Effect of Early Intervention

Natalya M. Lvoff

Department of Psychobiology
Occidental College
1600 Campus Road
Los Angeles, CA 90041
Faculty Advisor: Dr. H. Banis

The problem of child abandonment has long been neglected by society and preventive measures of this phenomenon remain poorly investigated. This study examined the rate of infant abandonment in two Maternity Hospitals in St. Petersburg, Russia from 1990 to 1995. Initially, both hospitals followed the traditional Russian practice of separating the mother and infant for 6-7 days after delivery. When one of the hospitals changed its practices to encourage early mother-infant contact, the abandonment rate at that hospital decreased by 34%. The abandonment rate in the control institution increased by 32% during the same period. Our results suggest that establishing early mother-infant contact may have a significant effect on infant abandonment.

BACKGROUND

Recent welfare reform has attracted strong attention to the problem of parental inadequacy and the phenomenon of infant abandonment (Frank, Klass, Earls & Eisenberg, 1996; Markel, 1995; Ralph, 1995). The rate of infant abandonment in the United States remains poorly investigated, although it has been estimated to be as high as 2% in some parts of the country (Abedin, Young & Beeram, 1993). International studies have shown that infant abandonment ranges from 0.4% in France (Dumaret & Rosset, 1993) and Thailand (Buranasin, 1991) to 4% in Romania (Johnson, Edwards & Puwak, 1993).

Numerous studies have shown that abandoned infants are at an increased risk for nosocomial infection (English, 1983; Frank et al, 1996), failure to thrive (Johnson et al, 1993), developmental delay, decline in IQ scores (Kaler & Freeman, 1993; Frank et al, 1996), permanent damage to personality and severe psychological disturbance (Burnstein, 1981). Despite the importance of the problem of child abandonment, research regarding possible preventative measures of this phenomenon has been very limited. Several reports have shown that establishing early mother-infant contact may reduce maternal inadequacy, including the rate of child abandonment (O'Connor, Viettze & Sherrod, 1980; Buranasin, 1991; Klaus, Kennel & Klaus, 1995).

This study compares the abandonment rate at two hospitals in Russia that follow different systems of mother-infant interaction during the early neonatal period. Both hospitals originally followed the strict Russian tradition of separating the mother and infant immediately after delivery and keeping them separated for the first week of life. One hospital, however, recently changed its practices to encourage early and prolonged interaction between the mother and her infant. The other hospital, acting as the control institution of this study, continues to separate the mother and infant at birth.

The problem of child abandonment has never been studied in the Soviet Union and post-communist Russia. The existence of the problem was denied and banned from discussion and publication for several decades (Lubimenko, 1996). The second goal of this study was to find reliable data on the rate of infant abandonment in the city of St. Petersburg and compare this to the rate of abandonment in other countries.

METHODOLOGY

The rate of child abandonment was studied at two large "Maternity Houses" of St. Petersburg, Russia over a six year period from 1990 to 1995. Maternity House #16 was chosen as the control institution because it continues to follow traditional Russian practices of separating the mother and infant at the time of delivery. Delivery service at Maternity House #16 follows the strict regulations of the Administration of Maternal and Infant Health of the Ministry of Public Health in Moscow. Six to eight mothers labor and deliver together and room together in the postpartum period. Immediately after birth, the infant is separated from the mother and taken to the nursery for an eight hour "stabilization period". The mother cannot see the infant during this time because she is in her "recovery period". If after eight hours of stabilization, the condition of the infant is considered satisfactory, the child is taken to the mother's room for a 30 minute feeding period under strict nurse supervision and then returned to the nursery. All feeding periods last only 30 minutes and occur six times per day. The infant remains in the nursery the remainder of the

BEST COPY AVAILABLE

time (21 hours per day). Rooming-in is not permitted and fathers and other family members are not allowed to visit the mother or infant.

The abandonment rate was compared to Maternity House #11, which recently changed its practices regarding mother-infant interaction. Until mid-1992, Maternity House #11 followed the same system with six to eight mothers laboring, birthing and rooming together and keeping the mother and infant separated during their hospital stay without family visitation. By the end of 1992, with the help of a Swedish medical team, the hospital converted its services to comply with the UNICEF Baby Friendly Initiative. All patient's rooms were converted to private and semiprivate. Delivery services were changed so that each mother would deliver in separate rooms and the baby would not be separated from the mother following delivery. The regular nursery was closed. Rooming-in is maintained from birth to the time of discharge. The mother takes complete care of her child and breast feeding is encouraged. Fathers and family members are allowed to visit. The rate of abandonment at both institutions was studied three years prior and three years following the implemented changes at Maternity House #11.

Maternity Houses #11 and #16 are both state-run hospitals. They are 2.8 miles apart and serve similar socioeconomic communities. Mothers are sent to the Maternity House that is in their residential district.

According to Russian law, an infant is considered to be abandoned when the mother leaves the Maternity House after signing a release transferring custody of her child to the state. The number of births per year and the number of abandoned infants was taken from the log books kept by the Chief Doctors at both Maternity Houses. Separation time of the mother and infant was investigated using the log books of the corresponding nurseries. The rate of abandonment was calculated per 1000 deliveries per year at each hospital. The number of abandoned infants and the number of births in St. Petersburg was obtained from the Central Statistics Board of the Department of Public Health of the City of St. Petersburg and was provided by the Chief Neonatologist of the city, Dr. V. Lubimenko.

RESULTS

Table 1 presents the number of deliveries, number of abandoned infants, and the abandonment rate calculated per 1000 births at Maternity Houses #11 and #16. The table shows that the abandonment rate at Maternity House #16 remained stable at 44-52 abandoned infants per 1000 births until 1993 and then increased by 32% from the 1990 level. At Maternity House #11, the abandonment rate remained stable until the end of 1992 and then decreased by 34% in 1993-95. This significant decrease in the rate of infant abandonment corresponds to the time of conversion to the Baby Friendly System.

According to the Central Statistics Board of the Department of Public Health of St. Petersburg, there were 34423 births in St. Petersburg in 1995 and 1997 infants were abandoned. In 1995 the abandonment rate in St. Petersburg was 58.1 per 1000 deliveries.

Table 1. Number of births and abandonment rate at Maternity Houses #11 and #16

Year	Maternity House #11			Maternity House #16		
	Number of Births	Number of Abandoned Infants	Abandonment per 1000 births	Number of Births	Number of Abandoned Infants	Abandonment per 1000 births
1990	2539	12	4.7	3810	177	46.4
1991	1842	10	5.4	3670	192	52.3
1992	2035	12	5.9	3368	176	52.3
1993	1835	6	3.3	3098	138	44.5
1994	1646	6	3.6	3824	219	57.3
1995	1981	7	3.5	3872	268	69.2

DISCUSSION

The high rate of infant abandonment has been a significant problem in Russia for many centuries. Social programs established during the era of Catherine the Great, including paying large fees to women to find abandoned infants and care for them actually encouraged the practice of abandonment and helped make it socially acceptable (Ransel, 1976). We found that the abandonment rate in St. Petersburg, Russia in 1995 was 5.8%, which is higher than the rates that have been reported in other countries.

Despite the importance of the problem of child abandonment, studies of possible preventive measures are very limited. It has been debated whether the first hours and days of life are a sensitive period for the mother (Klaus et al, 1995). O'Connor et al (1980) showed that increasing mother-infant contact by six hours on days one and two of life decreased child abuse in the first 17 months of life. Siegel et al (1980) however, did not find a significant difference in the frequency of child abuse in a study with a similar design, but did observe parenting differences at a later age. When the initial mother-infant separation time was reduced from 6.3 to 1.6 hours and rooming-in instituted in a Thai hospital, child abandonment declined from 33 infants per 1000 to one in 1000 (Buranasin, 1991). A similar decrease in abandonment was also described when early contact and rooming-in was introduced in Costa Rica (Mata, Saenz & Araya, 1988). R. Fuchs (1987) found that if indigent women in the seventeenth century France breast fed their infants for the first eight days or longer, the abandonment rate was significantly reduced.

While abandonment at hospital #11 dropped by 34% following implementation of early mother-infant contact, the abandonment rate at hospital #16 dropped by 14% during the same time period and then rose briskly in 1994-95. In hospital #11, the abandonment rate held steadily during these years. Since in Costa Rica and Thailand simply closing the newborn nursery and having all mothers room-in with their infants significantly reduced the abandonment rates, it is our impression that close and continual early contact for mother and infant with rooming-in is responsible for the drop in abandonment.

Our results suggest that institutional policies can have a significant effect on the development of mother-infant interaction and as a result can change a phenomenon as profound as infant abandonment. Encouraging early and prolonged mother-infant contact may provide a possible low cost intervention to the urgent problem of infant abandonment.

While divorce research had typically focused on the emotional and behavioral problems of the children involved, recent studies have found many of these problems to be eliminated if the adolescent has a positive relationship with one or both of their parents. The present study extends this research by studying the effects of parent child relationships on adolescent functioning with in two years of a parent's divorce and following up their functioning five years later. Results found parent-child relationships to be better predictors of adolescent functioning than parental marital status for life satisfaction, self-esteem. Marital status only affected the adolescent's security with romantic partners.

BACKGROUND

How a parent's divorce effects adolescent functioning is a widely studied area. Much research has found divorce to place added difficulties on adolescent functioning, such as behavioral problems in school and emotional distress (Wallerstein, 1983a, 1983b; Hetherington, Cox, & Cox, 1985). While these studies are accurate in predicting the outcomes in some families, there are adolescents who continue to function normally after their parent's divorce (Barber & Eccles, 1992). Researchers often take divorce as a single factor in adolescent development and group all children who have undergone a divorce together, without looking at individual family circumstances. Normal functioning is more apparent when additional factors involved in the divorce, such as the parent-child relationships, are investigated (Hess and Camera, 1979; Forehand, Middleton, & Long, 1987; Wierson, Forehand, Fauber, & McCombs, 1989; Black & Pedro-Carroll, 1993).

Hess and Camera (1979) demonstrated the need for researchers to look beyond whether a child's parents were simply divorced or married in predicting functioning. They examined participants from divorced and intact families on school and social behaviors and on their relationships with other family members. Hess and Camera found that the family relationships were more valid predictors of the child's behavior than marital status, and that positive relationships resulted in lowering the detrimental effects commonly associated with divorce.

Wierson, Forehand, Fauber, & McCombs (1989) also examined whether good parent-child relationships can help buffer the detrimental effects often associated with divorce in boys between the ages of 10 and 15. Wierson et al. found that the adolescents in the divorced group had significantly higher levels of functioning if they had a good relationship with at least one parent as compared to a poor relationship with both parents. When comparing adolescents from divorced and married families, there were no significant differences in functioning as long as the adolescent had a good relationship with at least one parent. These results suggested that parent-child relationships can serve as a buffer against the detrimental effects of divorce, and can be better predictors of the functioning of adolescent than the martial status of the adolescent's parents.

Along with Hess & Camera and Wierson et al. a number of other researchers have also found the parent-child relationship to be a more adequate predictor of adolescent functioning than parental marital status (Peterson & Zill, 1986; Forehand, Middleton, & Long, 1987; Black & Pedro-Carrol, 1993). While these studies have contributed immensely to the knowledge about divorce, they do contain many limitations. For example, many divorce studies involve very small sample sizes, making it difficult to generalize the results to a larger population (e.g., Hess & Camera, 1979). Some sample populations are also drawn from clinical support groups (Wallerstein, 1983a, 1983b). These participants may exhibit more difficulties than participants who were randomly assigned because they have already indicated problem behaviors that need to be changed.

Additional problems in the existing research on adolescent functioning after a parent's divorce lie in the lacking of longitudinal studies. While the long-term effects of divorce have been investigated, (e.g., Hetherington, 1989; Wallerstein, 1983a, 1983b), few of these studies look beyond marital status when predicting adolescent functioning. Also, few studies provide a control for functioning prior to the divorce to determine if the adolescent's always exhibited problem behaviors or if these behaviors are a result of the added stress and pressures after the divorce.

Using a longitudinal approach, the present study hoped to address many of the limitations in current divorce research by examining parent-child relationships as predictors of adolescent functioning. There were two main hypotheses in this study. First, it was predicted that adolescents who have close relationships with at least one parent will have better adjustment in young adulthood than adolescents who are not close with either parent, regardless of whether the adolescents' parents are married or divorced (Wierson, & Forehand, 1992). Second, it was predicted that adolescents who have close relationships with both parents will have better adjustment in young adulthood than adolescents who are close only with one parent, regardless of whether the adolescent's parents are married or divorced (Hess & Camera, 1979).

Participants were 311 young adults and their biological mothers, sampled from the community. These individuals were assessed during the target child's early to middle adolescence (adolescent phase), with a follow-up assessment when the child was one year post-high school or at least 19 years of age (young adult phase). At the time of the initial assessment, all subjects from divorced families had experienced the recent divorce (less than 12 months) of their biological parents, as resided with their mother following the divorce. Ninety-nine of the participants had parents with intact marriages. Approximately six years after completing the adolescent phase of the project, participants were contacted and asked to participate in the young adult phase. Relationships were grouped according to whether the adolescents had close relationships at the time of first assessment with both parents, one parent, or neither parent. Functioning was controlled for at time one through the general and social sections of the teacher RSCC Harter (Harter, 1982) and the Revised Behavior Problem Checklist (Quay & Peterson, 1987).

RESULTS

Separate 2(married v. divorced) x 3(good relationship with none, either or both) Analysis of Variance were performed with life satisfaction, security with romantic partners and the BSI positive symptom distress index as dependent variables. For life satisfaction, there were main effects for relationships (F=4.551, p<.05). A univariate analysis reveled that having a good relationship with both parents was better for life satisfaction than having a good relationship with just one or neither parent (t=2.37, p<.05) There were no significant effects based on whether the adolescent's parents were married or divorced for life satisfaction. For the Positive Distress Symptom Index, there were also significant main effects for the parent-child relationships (F=3.512, p<.05). There were no differences between having a good relationship with one or both parents. Again there were no significant main effects based on the marital status of the parents. For self-esteem, there was a main effect for parent-child relationships (F=3.819, p<.05). There were no differences between having a relationship with one or both parents or based on parental marital. For the security with romantic partners, there was a main effect concerning parental marital status with the children from married families being more secure in their relationships (F=10.620, p<.05). There were no reliable effects between parents-child relationships and the security level of the adolescents with romantic partners.

DISCUSSION

The results did provide some support for our hypotheses. Our first hypothesis predicted that adolescents who have close relationships with at least one parent will have better adjustment in young adulthood than adolescents who are not close with either parent, regardless of whether the adolescents' parents are married or divorced. Our results supported this for life satisfaction, distress symptoms, and self-esteem. For security with romantic partners, however, there were no significant differences for parent-child relationships, but the participants with married parents were significantly more secure with romantic partners than those from divorced families. These results are consistent Wierson, Forehand, Fauber and McCombs (1989) who also found close parent-adolescent relationships to act as a buffer against the detrimental effects of divorce.

Our second hypothesis predicted that adolescents who have close relationships with both parents will have better adjustment in young adulthood than adolescents who are close with only one parent, regardless of whether the adolescent's parents are married or divorced. The results only supported this concerning life satisfaction, where having positive relationships with both parents related to increased life satisfaction as compared to having a positive relationship with only one parent. The importance of parent-adolescent relationships on life satisfaction is consistent with the findings of Hess and Camera (1979) that having a good relationship with both parents is more beneficial than having a good relationship with just one parent. As far as distress symptoms and self-esteem, there were no significant differences between a positive relationship with one or both parents, and parent-child relationships again had no effect on security with romantic partners.

These results demonstrate the importance of parents maintaining good relationships with their children, regardless of their marital status. As far as life satisfaction, distress symptoms, and self-esteem, children from both divorced and married families functioned similarly as long as they had a good relationship with at least one parent, which provides support for results previously found by Wierson, Forehand, Fauber, and McCombs (1989). When children receive the adequate support and attention they need from their parents, parental marital status becomes less of an issue.

Despite there being significant differences between having a positive relationship with one and both parents in relation to life satisfaction, there were no differences concerning distress symptoms or self-esteem, contrary to what was previously found by Hess and Camera (1979) regarding the importance of positive relationships with both parents. While the children may have more satisfaction in their lives when they maintain good relationships with both parents, our study suggests that a good relationship with one just parent may provide the necessary support to alleviate distress symptoms and to help them maintain good levels of esteem. These results are similar to those found by Forehand, Middleton, and Long (1987) who found three stressors (divorce, poor relationship with mother, and poor relationship with father) to be indicative of more difficulties for adolescents than zero, one or two stressors. It seems that as long as the adolescent does not have to deal with all of these stressors at once, their functioning and distress symptoms will not be effected or impaired.

Our results did not support our hypotheses concerning the adolescent's security with romantic partners because the adolescent's relationships with their parents had no effect on their levels of security. Security with romantic partners did depend, however, on whether the adolescent's parents were married or divorced, with those from married families being more secure in their relationships. These results may indicate that adolescent's from divorced families approach romantic relationships with more caution because they have seen that not all marriages end happily. Wallerstein (1985) also found adolescents to be cautious in their own relationships to prevent a divorce in their own life. While being too insecure in relationships is not necessarily healthy, being cautious can help people think more when they are making decisions about life long commitments.

CONCLUSION

In conclusion, parents-child relationships seem to be better predictors of adolescent functioning than parental marital status as far as life satisfaction, self-esteem, and distress. Marital Status affected the child's security with romantic partners, but did not impair day-to-day functioning. This seems to show that a positive relationship with parents can eliminate many of the detrimental functioning problems often associated with divorce.

Dr. Manuel Carlos

Ethnography is the study of a people and their culture. Doing ethnography is compiling and researching according to specific ethnographic methods. It grows out of the field of cultural anthropology. The primary element in doing ethnography is direct contact with the people to study their belief systems, economic systems, social engagement and interaction rules, dispute settlements, human behaviors, religion, educational systems and how they go about their daily lives. It has gone from being a speculative enterprise to doing field research. In the early days of ethnography, distant cultures were studied by talking to the missionaries who had been with them upon their return. So the ethnographic study was done in the office at a desk. This led to a biased study - biased both by the person reporting the behaviors, and by the person interpreting the report and writing the study. Eventually, as ethnography became more important, it was figured out that the only way to do a true ethnography is to go out into the field and live with the people being studied.

Robert Redfield was the first American anthropologist to do this in Mexico. In the 1930's he published two books as a result of his studies which discussed his theory of the folk urban continuum. That continuum's subject was how folk villages interact with, and become dependent on, close urban communities. That theory could not have been properly developed without doing field work.

With field work being so important in doing a successfull ethnograhic study, how does one learn field methods in the classroom? Well, you can read books on research methods and you can practice these methods by doing local community studies. But in both of these cases, you remain in a familiar environment without the obstacles that would be encountered in a foreign setting. Now there is a way to experience a foreign ethnography, without incurring the costs of money and time it would take to travel to another country. The way to do this is by utilizing an ethnographic simulator. The military uses simulators to play out a war and the different solutions, and now the field of ethnographic research is able to use a simulator to study an entire population.

I have been using just such a simulator to study an indiginous population in the state of Queretaro, Mexico. The simulator offers not only the interesting components of doing field research, such as interviews with new and interesting people, but also obstacles such as language barriers, and different answers for different gendered interviewers, and a limited budget.

As the simulation began, I arrived at the bus station in Queretaro City. My first assignment was to familiarize myself with public transportation. I found the bus station to be very large and clean with many terminals and travel destinations and comparable to an American airport. There was a place to pray for safe travel and for the safe arrival of friends and relatives. There were also food stands as well as a small market. There is a choice of two types of buses to travel on - a luxury bus and an economy bus. The luxury bus is large and very clean with leather seats, a television, a restroom, snacks and attendants. The people who travel on the luxury liners are wealthy citizens and tourists. The economy bus seemed comfortable enough and it was fairly clean, but the seats were well worn and marked with scratches and graffiti. The most common passengers on the economy bus are the people who live in the rural areas and are carrying their goods to and from market places. Many of them are the indigineous Otomi people who are distinguishable by their clothing. The Otomi women usually wear long colorful skirts and blouses, aprons and rebozos, which are rectangular pieces of cloth used to cover their shoulders or their heads. Many of them as well as the men, also wear straw hats. As I traveled on the economy bus, I was serenaded by a man singing and playing the guitar up and down the bus aisle, which is very common in Mexico and a way to earn money through tips.

The biggest problem I encountered, and probably would have encountered had I actually been in the field, was using up all of my budget and alloted time because I was having so much fun and went on to do more than my assignmet asked of me. So in this case I learned that an important part of doing an ethnographic study, is sticking to the task at hand.

My next assignment was to take a walking tour of the city of Queretaro, writing an ethnographic description of the public places, people, urban life, and material culture. I found the streets of Queretaro to be a very divers scene. Most of the buildings are constructed of stone or brick, or some other concrete material. The architecture is mostly of a Spanish style with a lot of iron ornamentation. There is not much built in a more modern style, not even the newer buildings. The people on the streets presented a full range of style and dress. There were casually dressed people, who could be students or people who work in a job where casual dress is appropriate. There were also more formally dressed people, who could be people that hold office jobs or people of a higher social class. There were also many people dressed in well worn clothing and hats, who could be field workers, as well as many traditionally dressed Otomi people. I found many arts and craft stands on the streets selling hand made items which ranged from religious items to touristy dolls and souveniers. The plaza's were very beautiful and well kept with flower gardens, gazebos and fountains. In these plaza's, I found people chatting with friends, lounging around, and people watching while the children played and enjoyed the fountain. The modes of transportation appeared to be mainly walking, and there were a lot of buses and people at the bus stops. I didn't notice too many older persons walking along the streets, but I did notice them sitting in the plaza's and selling arts and crafts. The median age of the general "street populating", and this is not to be confused with "homeless street people," seemed to be in the early 20's.

The biggest problem I encountered with this assignment was that I had no way of knowing what time of day it was. I would have preferred to have done this at specific hours of the day, such as early morning, late morning, lunch, late afternoon, evening and night time in order to do a comparison.

My next assignment was to visit the headquarters of the National Institute for Indigenous Affairs, which will be referred to as the INI, and describe the programs and functions. The INI is in charge of dealing with problems that the indigenous population faces. For example, as a result of NAFTA, the peasants have sustained a substantial loss with fertilizer use, so the INI helps them by covering some of the costs of fertilizer. They are also taking a loss with corn, so the INI is trying to get the producers to diversify their production by extablishing programs for floriculture, livestock raising and the production of fish, and it is the INI engineers who are assisting them. Another project of the INI is direct commercialization of the crops by establishing an agreement through which the producers of the area will supply grains to other indigenous communities. They are promoting arts and crafts like textiles and pottery and in the last few years, the INI has financed up to 65 of these projects. With one of the biggest problems of indigenous people being alcholohism, the INI has established a health care program in eight communities. The program includes first aid classes, illness prevention measures and others. There has also been an attempt to train a number of translators to help diminish unemployment due to discrimination. They provide funds for cultural projects such as the construction of monuments, traditional dance and musical group promotion. One of the main problems of the INI is the lack of support from the staff. It seems that many have forgotten that they are there to help the people and only work for personal gains.

This information was obtained by conducting an interview with the head of the INI, and so the problem I encountered was having to pay an interpreter to translate for me. I also would have liked to have visited some of the health centers, but this was not offered to me in the simulator.

My next assignment was to travel to Tixtha, locate a folk healer named Dona Severiana and interview her in order to make an inventory of curative plants and the ailments they cure. I found Dona Severiana to be an old woman who lives in seclusion and is paid minimally by the government to raise these very interesting curative plants. She learned the secrets of the trade from her mother and recieved training from the government that she had to pay for, which in turn enabled her to be paid by them. The following table illistrates the names of the plants and there cures.

BEST COPY AVAILABLE

Epaote, Wormwood, Chenopoduim ambrosoides	Cures susto, the fright, amebiasis, amenorrhea, anemia, arthritis, asthma, colic, fever, stomach aches and rheumatism. Also used as a spice.
Sauco, Elderberry, Sambucus Mexicana	Cures coughs, colds, rheumatism, bronchitis and is used sudorific.
Poleo, Pennyroyal, Hedeoma Pulgiodes	Cures stomach cramps.
Cedron, Simba Cedron	Cures stomach cramps.
Topozan	Used to make soap and cures stomach cramps.
Manrubia, Horehound, Marrubium Vulgare	Cures cramps
Romero, Rosemary, Rosemarinus Officinalis	For bone and muscle aches
Hierbabuena, Spearimint, Hedoma Piperita	Cures stomach aches.
Hinojo, Fennel, Foeniculum Vulgare	Cures "air"
Trementina, Pinus Edulis	Cures bone fractures.

Figure 1: Curative Plants

I found this assignment to be very interesting because of the colorful pictures of the different plants and the interesting ailments they cure. Also Dona Severiana presented a very interesting character.

My next assignment was to take a taxi to the State Council of Population in the downtown area of the city, locate and access data on population to find the five largest and five smallest counties in the state of Queretaro. The following table illistrates this information.

Largest Counties	Population
Amealco de Bonfil	46,358
El Marques	55,258
Queretaro	456,458
San Juan Del Rio	126,555
Cadereyta	44,944

Smallest Counties	Population
San Joaquin	6,229
Arroyo Seco	13,112
Penamiller	16,155
Toliman	17,990
Landa de Matamoros	17,964

Figure 2: County Populations

This was a very easy assignment to complete and probably the most boring. However, the important thing to remember when doing an ethnographic study is the boring stuff is just as important as the fun and interesting components.

My last assignment was to locate to key informants named Don Jose and Don Miguel, interview them, and report on their different views of religion, farming activities, housing and dress. Don Jose is an Otomi social leader who is involved in organizing festivals and events, which includes things such as, finding dancers and people to cook the food and provide the alcohol. He exchanges favors with different people in the community for food, alcohol and other things for the festivals. He believes in a social status way of life, customs and ceremonies and feels it is all interconnected. Don Miguel is a Mestizo political leader in the community. He feels that there is a degree of seperation between civil and religious events. He also feels that everybody gets along fine and that there is no prejudice among the Otomi and Mestizo population, which I have found to be untrue.

This was another interesting assignment to complete because of the views of the leaders from two different groups. I also found it interesting that it was the man from the dominating group that felt there is no prejudice. The problem I had in completing this assignment was that once again I had to pay a translator in order to conduct the interview. Because of this, the information that I recieved was a little different than what I would have recieved had I spoken and understood the language myself.

The wonderful thing about using this simulator is that I was able to do a fairly thorough ethnographic study without having to incur the expense or time that would have been spent had I actually gone to Queretaro, Mexico. Equally great is the fact that I was able to learn how to do an ethnographic study while doing it.

Irrelevant Speech Eliminates the Word-Length Effect

Rebecca Mazzorana

Ian Neath and Aimee Surprenant

The working memory model has been used to explain word-length effect: short words are easier to remember than long words. According to the working memory model, the word-length effect occurs because of subvocal rehearsal in the articulatory loop. There should be no interaction between the word-length effect and irrelevant speech, according to the working memory model. An experiment was conducted to test this prediction. Contrary to the prediction, there was an interaction. Irrelevant speech eliminated the word-length effect for auditory items in the experiment and visual items when the experiment was modified. The current experiments do not support the predictions of working memory; rather, they are best interpreted as supporting an alternative model such as the feature model.

BACKGROUND

The word-length effect describes the finding that individuals can better remember words that take less time to pronounce than words that require a longer pronunciation time (Neath, Surprenant, LeCompte & Byun, 1996). This effect is observed with free and serial recall for both auditory and visual items (Watkins & Watkins, 1973). Baddeley's working memory model and Nairne's feature model offer competing explanations for this phenomenon (Neath & Surprenant, 1996).

In the working memory model, the "phonological loop" is of primary importance (Neath & Surprenant, 1996). It contains two main components: the phonological store and the articulatory control process. Speech-based information is retained in the phonological store for a short period of time. Traces within the store are assumed to degenerate in approximately one to two seconds, if they are not used (Neath, et al, 1996). The articulatory control process translates visual information into a speech-based code and refreshes decaying traces in the phonological store to offset the decay process. If rehearsal of a particular item does not occur within a certain time, the memory trace for that particular item will have decayed too far to be usable.

Thus, the amount of verbal information that can be retained is dependent on the rate of decay and the covert rehearsal rate. According to the working memory model, an item that takes longer to pronounce will take longer to be covertly rehearsed, because the articulatory control processes are related to the covert speaking rate. Thus, short items are more likely to be rehearsed before decaying than long items, and this will result in better recall of short items (Neath et al., 1996).

Unlike the working memory explanation, the feature model holds that no one feature (e.g. length) in a word is meaningful (Nairne, 1990). According to the feature model, primary memory (storage of short term information) has no capacity limit, and items in primary memory do not decay. One function of primary memory is to construct and maintain cues that may indicate which items were presented on a particular list (Nairne, 1988, 1990).

Another main difference between working memory and the feature model is that, whereas the central forgetting process in working memory is time-based decay, the feature model states that loss of information is due completely to interference (Nairne, 1988, 1990). New items interfere and disrupt items that are already in primary memory.

The two models also make different predictions about recall performance against a background of irrelevant speech. According to the working memory model, the irrelevant speech items enter the phonological store and interfere with the information about the to-be-remembered items (Salame & Baddeley, 1982), which produces an overall decrease in performance. Irrelevant speech is not believed to have an impact on the word-length effect.

According to the feature model, the additional features from the irrelevant item-whether spoken or heard-increase the likelihood of a mismatch, and thereby reduce recall. The feature model predicts that irrelevant speech will eliminate the word-length effect for visual items (Neath et al., 1996).

In the current experiment, the objective was to examine whether irrelevant speech would eliminate the word-length effect as the feature model predicts. If this is the case, participants would demonstrate equal ability in recalling long and short words correctly, by matching the degraded primary memory traces with the appropriate intact trace in secondary memory.

MATERIALS/METHODS

Part 1. Forty participants were tested in one of two conditions: (a) Silent Condition and (b) Tea Time Condition. In the Silent Condition participants were asked to remember the order in which they heard eight different words through headphones. After the final word, the eight words appeared on a computer screen in alphabetical order, and the participants were to click on the words in the order in which they heard them (reconstruction of order task).

The Tea Time Condition consisted of the same procedure with the exception that the participants were instructed that, in order to increase the difficulty of the task the words "tea time" would be repeated continuously during presentation and recall. The to-be-remembered items were audible in one ear, while the interference (tea time) was audible in the other ear. The participant's task was to filter out the interfering stimuli and recall the eight words presented in each list.

Part 2. An additional 40 students then participated in a modification of the above procedure. Word lists were presented visually and were reduced to five words per list. After viewing the words, participants were asked to write down the words in the order in which they were seen (written serial recall). The words "tea time," were presented over headphones for half of the lists for all participants.

Part 1 was a between subjects design, and Part 2 was within subjects.

RESULTS

With a quiet background, there was an overall advantage in performance of short over long words (0.538 vs. 0.517 respectively), $F(1, 34) = 4.30$, $MSE = 0.016$, $p < .05$. This was qualified by a significant Word Length x Background Condition interaction, $F(1, 34) = 4.21$, $MSE = 0.016$, $p < .05$. There was a typical main effect of serial position, $F(7,238) = 92.47$, $MSE = 0.018$, $p < .01$. The Word Length X Serial Position interaction was not significant. See table 1 for mean proportion correct and mean standard error.

Table 1: Auditory presentation
Long and short words manipulated within subjects
Silent versus irrelevant speech manipulated between subjects
Reconstruction of order task

CONDITION	MEAN PROPORTION CORRECT	STANDARD ERROR
SILENT SHORT	0.5903	0.0245
SILENT LONG	0.5498	0.0254
TEA TIME SHORT	0.4863	0.0287
TEA TIME LONG	0.4852	0.0252

N = 18 per group

842

For the visual presentation, there was an overall advantage in recall of short over long words (0.774 vs. 0.640, respectively), F(1, 17)= 72.78, MSE = 0.021, p < .01, the Word Length X Background Condition interaction was significant, F(1, 17) = 69.39, MSE = 0.016, p < .01. There was a typical main effect of serial position, F(4, 68) = 58.02, MSE = 0.025, p < .01. There was a significant interaction effect between Word Length and Serial Position, F(4, 68) = 4.26, MSE= 0.013, p < .01. There was no interaction between Background Condition and Serial Position, F(4, 68) = 1.56; MSE = 0.016, p > .19. The three-way interaction was significant, F(4, 68)= 4.54, MSE = 0.013, p < .01. See table 2 for mean proportion correct and mean standard error.

Table 2: Visual Presentation
5-item lists
Everything within-subjects
Written serial recall

CONDITION	MEAN PROPORTION CORRECT	STANDARD ERROR
SILENT SHORT	0.822	0.032
SILENT LONG	0.641	0.056
TEA TIME SHORT	0.665	0.057
TEA TIME LONG	0.064	0.052

N = 18 per group

CONCLUSIONS

With no irrelevant speech (Silent Condition), there was a significant increase in the number of correctly recalled short words as opposed to long words for both tasks. For the Tea Time Condition, there was no significant difference between the number of short words correctly recalled and the number of long words correctly recalled for both tasks. It is possible that the working memory model's interpretation of the word length effect or its interpretation of the irrelevant speech effect (or both) is incorrect. The feature model is supported.

Activational Effects Of Testosterone On Sound-Guided Spatial Navigation

Erin J. Moseley

Faculty Advisor:
Mark C. Zrull, PhD

Exposure of the brain to sex steroids during critical periods of development leads to many sex differences including those in spatial navigation ability. These organizational effects of hormones produce "male and female" brains that respond differently to sex steroids later in life. In this study,the activational effect of testosterone propionate (TP) on adult, Long-Evans rats' ability to navigate through Hebb-Williams mazes using sound cues to guide movement to a water reward was examined. Sexual differentiation was manipulated during early postnatal life to produce 5 groups of Long-Evans hooded rats that would exhibit different responses to TP during adulthood: females, masculinized females, males, demasculinized males, and castrated males primed with TP. As adults, rats navigated mazes after TP or control injections. Noise bursts were presented during maze trials to indicate the correct navigational path. TP improved maze performance for all groups except control males ($p < .05$). The results show that the sex steroid testosterone appears to have an activational effect on sound-guided spatial navigation in addition to the known organizational effect of this sex hormone on visuo-spatial learning.

INTRODUCTION

Males and females differ from one another in a variety of ways. These male-female differences begin early with the sexual differentiation process and are evident in features of the body, development of the brain, and sex typical behaviors. During early development the sexual differentiation of the brain is mediated by hormones secreted by the gonads (Breedlove, 1992). Levels of circulating hormones have a direct effect on the development of brain structures and result in a brain that is either masculine or femine. Testosterone and estrogens are hormones that act during development with resulting effects that are called organizational. Organizational effects transpire around the time of birth and can only occur during a critical or sensitive period and result in structural changes in the brain that are permanent and irreversible (Breedlove, 1992). For example, differences are apparent in certain sexually dimorphic areas of the brain such as the hypothalamus, which includes specialized nuclei that function as centers for regulation of the endocrine system. Specifically, the medial preoptic area (POA) of the hypothalamus contains a nucleus that is much larger in males than females. This difference is so apparent it can be observed without a microscope. Early exposure to testosterone, an androgen which is aromatized to estradiol (an estrogen), influences the size of this nucleus. Limiting androgens in males results in a smaller, less masculine POA, and females treated with an androgen or estrogen develop a larger POA. Other areas of the brain, including the hippocampus which is involved in the control of learning and memory, are also "organized" by early hormone exposure (Roof, 1993). This sexual dimorphism in brain regions results in sex typical behaviors. For instance, males often exhibit more aggressive behavior than females which can be related to hypothalamic differences, and males tend to be better at spatial learning and memory tasks than females which can be related to hippocampal sex differences.

While organizational effects occur at very specific times, sex steroids also influence behavior throughout the lifespan. Most of these effects can be called activational because the presence of a hormone intiates or modifies some behavior for a specific period of time only. Optimal activational periods occur when the testes and ovaries are active; for example, during puberty and adulthood (Zimmerberg & Farley, 1993). Activational effects are transient in nature, and often an animal's hormonal state at a specific time activates a particular behavior (Zimmerberg & Farley, 1993). Certain sex-related behaviors of males (e.g., mounting) and females (e.g., lordosis) are activated by the action of sex hormones in hypothalamic areas (Breedlove, 1992), and spatially organized, sexually dimorphic behaviors may be altered by the presence of sex steroids. For example, low testosterone levels in men and high testosterone levels in women are correlated positively with various spatial abilities (Kimura, 1993). Differences between male and female rats' behavior are observed in spatial navigational tasks particularly when the environment to be navigated, usually a maze, is familiar (Williams, Barnett, & Meck, 1990).

BEST COPY AVAILABLE

Spatial ability can be assessed in a variety of ways, with the most common being an examination of animals' navigation within a maze. Navigation behavior in an expected maze, or a familiar environment, depends upon experience in the specific environment. When features of an environment remain constant, an animal is able to build a cognitive representation of the environment as a whole (Williams et al., 1990). Cognitive mapping requires an animal to interact with an environment while charting a course to some distant goal (O'Keefe & Nadel, 1978). A citical aspect of cognitive mapping is the neural source from which it is generated, the hippocampus. The hippocampus has been implicated in mediating spatial navigation abilites and also in the process of working memory (Olton, 1982). Successful navigation in expected environments can be measured as overall performance across testing sessions, as well as working memory performance which refers to animals' memory for learned navigational strategies within a session. Sex differences between males and females relate to the preferential use of available distal environmental cues, and males generally outperform females in expected environments from which cognitive representations may be formed (Williams et al., 1990).

Observed sex differences in spatial navigation strategies are attributed to the organizational effects of gonadal hormones on the hippocampus and other brain areas which mediate spatial learning and memory (Roof, 1993). Few studies have investigated the activational influence of sex steroids on spatial abilities (e.g., Kimura, 1993) and the results are inconclusive. Generally, spatial navigation tasks dependent on visuospatial cues are used to examine sex differences (e.g., Roof, 1993); however, Zrull, Dyche, and Bowman (1994) demonstrated that distal sound stimuli can be used as cues to aid in navigational behavior.

While research on hormonal manipulations (e.g., Roof, 1993; Williams et al., 1992) supports the idea that spatial learning and memory is organized by early exposure to sex steroids, the activational role of gonadal hormones on spatial tasks is less clear (e.g., Kimura, 1993). Investigations of both organizational and activational effects of androgens and estrogens on spatial navigation have almost exclusively used paradigms in which distal visual stimuli provide cues important for task completetion (e.g., Joseph et al., 1978). The goal of the present study was to examine the activational effect of an androgen, in this case testosterone, on spatial navigation through familiar mazes guided by distal sound cues.

METHODS

Long-Evans hooded rats ($\underline{N}$=33, Harlan Sprauge-Dawley) were subjects. Prior to weaning, the animals were housed with their dams, and as adults they were group housed in plastic shoe-box cages. Rats had free access to food and water until behavioral testing began when water was obtained during testing sessions and freely for 36 hr on the weekends. The animal colony was temperature-stable (23 °C) and provided a 12 hr-12 hr light-dark cycle.

Within 24 hr of birth all rats were anesthetized by hypothermia. After sex was determined, the females were allowed to warm and recover and were then returned to their dams. Female pups were injected (sc) with 10 µg estradiol benzoate in 0.02 mL sesame oil (FEST, $\underline{n}$=10) or sesame oil only (FCON, $\underline{n}$=8) on postnatal days 1, 3, 5, 7, and 9. Male pups were placed in a supine position and castrated bilaterally through an incision in wall of the abdomen between the umbilicus and the genital papilla or incised but not castrated (MCON, $\underline{n}$=7). Castrates received sesame oil injections after surgery (MCAS, $\underline{n}$=4) or received priming injections of testosterone propionate (MCTP, $\underline{n}$=4, 250 µg in 0.05 mL sesame oil, sc). Males were then allowed to warm and recover, and were then returned to their dams.

Behavioral testing was conducted when rats were adults (60 or more days old) in a sound-proofed room (32 dB re 20 $\mu N/m^2$ ambient noise level). A modified Hebb-Williams (Hebb & Williams, 1946) maze which consisted of a raised circular platform with start and goal platforms and moveable barriers of varying lengths was used to assess spatial navigational ability. The goal areas were equipped with stainless steel tubes through which a water reward could be delivered. Moveable speakers (Realistic 40-1289A), which were hidden from view, surrounded the maze and were used to present sound cues to guide navigation through the Hebb-Williams mazes. Sound cues always indicated the error-free route to navigate a maze and consisted of a series of noise burst pairs (2 X 100 ms, 2-16 kHz, 50 dB) controlled by the experimenter. Each navigation trial was monitored by the experimenter and a videotape record was made. Navigation was quantitified as the the number of blind-alley errors, or deviations from the most direct route between the start and the goal, made by each rat on each trial.

Behavioral testing was the same for all groups after exploration of the open maze (no barriers) and gradual introduction of barriers. After rats consistently left the start platform and navigated around two barriers to the goal, a series of 16 sessions of 4 trials through familiar mazes were run. In this condition, a single maze was used for 4 sessions of 4 trials, and the maze was changed for each subsequent block of 4 sessions. Distal sound cues were always avaliable to guide navigation. Subsequently, rats from each group were given injections of 250 µg TP in sesame oil or the oil vehicle only 72, 48, and 24 hr prior to a second series of 16 navigation sessions. Injections continued every 24 hr until completion of the this activational series of sessions through different familiar mazes. Table 1 summarizes the conditions of the experiment, and Figure 1 shows examples of Hebb-Williams maze patterns.

Table 1. Number of Rats Run in the Activational and Organizational Conditions

Activational	Organizational Treatment				
	Female		Male		
Injection	Control	Estradiol	Control	Castration	Castrate+TP
Testosterone	4	6	3	4	4
Control (oil only)	4	4	4	4	4

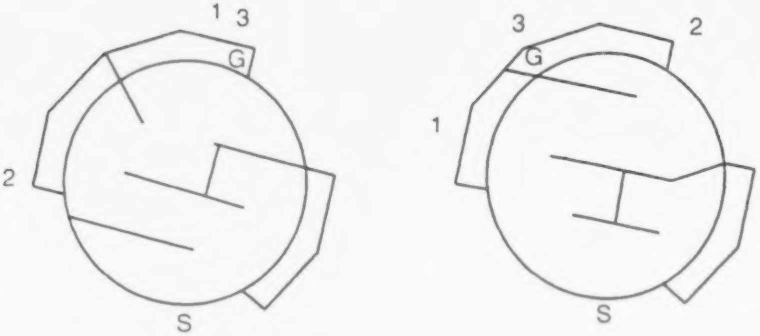

Figure 1. Diagrams of Hebb-Williams Mazes
This figure shows two examples of maze patterns used in the experiment. The numbers indicate the location and sequence of sound cues. S, start area; G, goal platform.

RESULTS

Two measures of performance were collected and analyzed for the experimental groups across the final 16 (i.e., activational) navigation sessions. The number of trials run with at least 1 error was used as a global measure of performance, and the percent of possible errors made on Trials 2 through 4 of each session was used as a spatial working memory variable. For each dependent variable, ANOVA was used to identify significant differences among the experimental groups relative to injections of TP and injections of oil only (i.e., no TP).

Overall navigation performance in the sound-cued familiar mazes was affected by the interaction of experimental group and TP injection, $F(4, 33) = 5.25$, $p < .01$. When injected with TP, female (FCON, -33%, FEST, -48%) and castrated male animals (MCAS, -63%, MCTP, -71%) ran fewer trials with at least 1 error than after oil vehicle injections (see Figure 2). In contrast, normal male rats (MCON) injected with TP averaged +100% more trials with error than male controls not injected with TP (see Figure 2).

Spatial working memory was affected by the interaction of experimental group and TP injection during Trials 2 through 4 of sound-cued navigation through the familiar mazes, $F(4, 33) = 8.97$, $p < .01$ (see Figure 3). When injected with TP, female rats (FCON) and female rats treated with estradiol showed -84% and -82%, respectively, decreases in the percentage of possible errors per trial. Similarly, both castrated male and castrated and primed with TP animals showed a decrease (-92%) in the percentage of possible errors across Trials 2 through 4 after TP injections relative to performance after oil vehicle injections. Like overall performance, normal male rats (MCON) injected with TP averaged a greater percentage of possible errors per trial than male controls not injected with TP (see Figure 3). For the working memory variable, the effect of TP was to increase the percentage of possible errors dramatically (+513%).

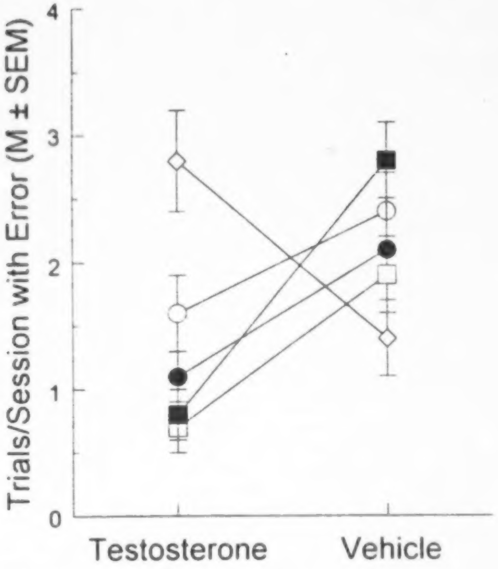

Figure 2. Overall Performance on the Sound-guided Navigation Task.
The graph shows the average number of trials with at least 1 error per session for rats in ○ female, ● female+estradiol, ◇ male, □ male castrate, and ■ male castrate+TP groups with and without activational testosterone propionate (TP) injections.

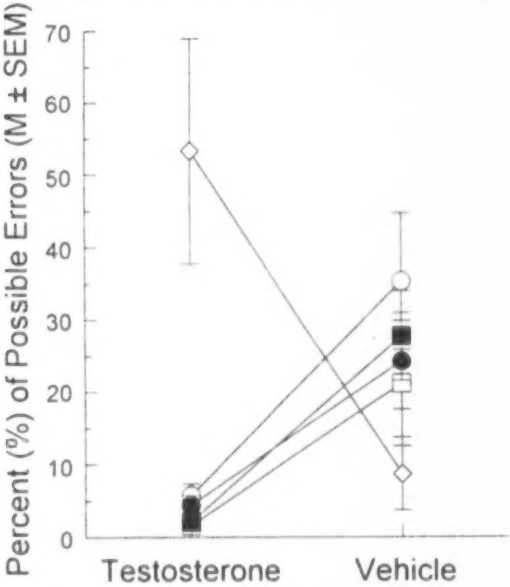

Figure 3. The Use of Spatial Working Memory in the Sound-guided Navigation Task.
The graph shows the average percent of possible errors on Trials 2 through 4 for rats in ○ female, ● female+estradiol, ◇male, □ male castrate, and ■ male castrate+TP groups with and without activational testosterone propionate (TP) injections.

DISCUSSION

The goal of this study was to examine the activational effect of testosterone exposure on an aspect of spatial learning and memory. Specifically, sex differences in developmentally manipulated male and female rats were examined for sound-cued spatial navigation through expected or familiar mazes. All animals, without regard to injections of TP, were capable of learning and completing the task indicating an ability of female, masculinized female, male, and demasculinized male rats to navigate mazes in a paradigm designed to facilitate cognitive representation or "mapping" (O'Keefe & Nadel, 1978; Williams et al., 1990). Like results of Zrull et al. (1994), distal sound cues in this study appeared to provide information that aided navigation. Performance was influenced by the sex of animals not exposed to testosterone with males, as expected (Joseph et al., 1978; Roof, 1993; Williams et al., 1990), out performing females and demasculinized males (see Figure 2).

Exposure to testosterone altered the overall task performance of all groups and had the greatest effect on MCTP rats which was indicated by the greatest decrease in trials with at least 1 error (-71%). Similarly, MCAS (-63%), FEST (-48%), and FCON (-33%) navigated with fewer errors after TP injections. Increasing the circulating testosterone in MCON rats also influenced spatial navigation performance. However, these activational effects of TP had an adverse outcome for the male animals with their performance characterized by a dramatic increase in the number of trials run with at least 1 error (100%). These results are consistent with past research (Roof, 1993) that demonstrated optimal levels of circulating testosterone, rather than excessive levels, are crucial for spatial navigation. Basically, an unusually low or high level of testosterone has an adverse effect on male spatial navigation performance and spatial ability in general (Kimura, 1993).

The activational influence of testosterone was also apparent for the spatial working memory component of the current spatial navigation task. With normal levels of circulating testosterone, male and masculinized female rats tend to make a lower percentage of possible errors when navigating a known environment than normal female rats (see Figure 3). Like overall navigation ability, spatial working memory was influenced by increasing the level of testosterone in an animal. Demasculinized male (MCAS, MCTP) and all female (FCON, FEST) rats decreased the percentage of blind alley errors made by at least 80% when given TP injections. MCON performance declined significantly with additional circulating testosterone (+513% of the possible errors per trial). The activational effects of testosterone on spatial navigation performance were expected to and did provide support for the hypothesis that there is a optimal level of this hormone with regard to spatial ability (Kimura, 1993). Too much testosterone causes males to exhibit poor spatial ability (Roof, 1993) particularly in this navigational task that is dependent on acousto-spatial cues.

Effects of Employment on College Students' Academic Performance and School Involvement

Laura A. Schwarber

Department of Psychology
Xavier University
3800 Victory Parkway
Cincinnati, OH 45207-6511

Faculty Advisor:
Cynthia L. Crown, Ph.D.

Researchers disagree about whether part-time employment promotes or hinders college success. Questionnaire data from 99 Xavier University undergraduate students were used to investigate the relationship among students' employment status, academic performance, and school involvement. A self-report questionnaire that focused on four measures: (i.e. GPA, frequency of unexcused class absences, and average time spent on homework and school activities) was administered. Based upon previous research, it was hypothesized that academic performance and school involvement significantly decrease for students working more than 20 hours per week. A correlation coefficient indicated no relationship between academic performance and college employment; however, participation in school activities was related to hours employed per week.

BACKGROUND

There seems to be endless debates concerning the costs and benefits of an adolescent holding a part-time job during his or her high school years. Having advocated for high school employment, the President's Science Advisory Committee (1973) argued that the nation's academic school system does not include many of the needed learning opportunities for students. The committee claimed that employed high school students can learn not only vocational and social skills but also gain the opportunity to take on more individual responsibility. In addition, employed students are exposed to real-world workplace experiences that may complement their future goals and aspirations.

Research has found that in some instances employment while in school can have positive consequences. In one such study Steinberg, Greenberger, Jacobi, and Garduque (1981) found that high school adolescents with work experience may develop increased social sensitivity, insight, and better communication skills. D'Amico (1984) found that employment had no negative effects on high school class rankings. However, employment effects did seem to vary depending upon the intensity of the work involved.

Yet, there are many studies that have found that working seems to be in some instances associated with lower academic achievement and school involvement. Steinberg and Dornbusch (1991) indicated that high school students who work long hours tend to have lower grades, less involvement in school activities, and a general disinterest in school as is reflected in their frequent class-cutting. This significant drop-off in school performance occurred among those students working more than 20 hours per week. Long work hours also detracted from other important learning experiences such as participation in school activities.

Though there are numerous studies on how employment affects high school adolescents, there is fairly limited research revealing the effects of employment on full- time college students. Does intense employment (i.e. over 20 hours per week) promote a sense of autonomy, responsibility, and accomplishment? Or, is working long hours a hindrance to college students' academic life and already demanding schedule? The purpose of the proposed study is to examine the effects of no employment (0 hours per week), moderate employment (1-20 hours per week), and intense employment (over 20 hours per week) on college students' academic performance and participation in school activities.

BEST COPY AVAILABLE

METHOD

Participants

Ninety-nine full-time undergraduate students (41 men and 58 women) from Xavier University volunteered to participate in this study.

Procedure

A questionnaire that took approximately five minutes to complete obtained background information on participants' sex, year of undergraduate study, age, and work intensity (i.e. number of hours worked per week). Of primary interest are two outcome measures in relation to employment status: 1) academic performance and 2) amount of participation in school related activities.

Academic Performance

Three indices of academic performance were assessed. Students provided information on their current overall grade point average based on a 4.0 scale, the average amount of time spent on homework daily, and their frequency of unexcused school absences per week (i.e. the average number of times he or she cuts class).

School Activities

Measuring of the amount of school involvement was based on the response to the following question: "On the average, what is the amount of time you spend weekly on school related extracurricular activities including clubs, athletics, school committees, or school related volunteer services?". Intervals for this question ranged from "0 hours per week" to "more than 6 hours per week".

RESULTS

As is evident, 84% of participants were employed, and almost 38% were working more than 20 hours per week. (See Table 1). The participants' average hours worked per week was between 16- 20 hours (M=4.363, SD=2.247). Because participants reported answers in terms of intervals, means and standard deviations were also reported in terms of interval level. Thus, a GPA overall sample mean of 3.854 represents an interval level of 3.1-3.5 as is described under "description and coding" in Table 2. The 4 outcome variables (i.e. GPA, time daily spent on homework, amount of weekly class-cutting and school activity participation) are also summarized by gender in Table 2.

Table 1
Work Intensity by Gender

	Male		Female	
Variable	n	%	n	%
Hours worked /week				
0	7	14.14	9	9.09
1-5	3	3.03	3	3.03
6-10	4	4.04	2	2.02
11-15	4	4.04	10	10.10
16-20	6	6.06	13	13.13
21-25	5	5.05	9	9.09
26-30	5	5.05	9	9.09
30 or more	7	7.07	3	3.03
	n= 41		n= 58	
Total cases = 99				

Table 2
Overall Means and Standard Deviation of Outcome Variable by Gender

		Male			Female	
Variable Description and Coding	M	SD	L	M	SD	L
GPA Overall grade point average on 4.0 scale. Intervals range from 1= (1.0-1.5) to 5= (3.6-4.0)	3.854	.8234	(3.1-3.5)	4.121	.7511	(3.1-3.5)
Homework Average time spent on homework daily. Intervals range from 1= (0.5 hrs/day) to 7=(more than 5.5 hours/day).	3.000	1.245	(2.0-2.5)	3.241	1.247	(2.0-2.5)
Class-Cutting Average time participant cuts class each week. Intervals range from 1= (0 times/wk) to 5= (4 or more times/wk).	1.756	.7994	(1 time/wk)	1.414	.7017	(0 times)
School Activities Weekly average participant spends on school related activities. Intervals range from 1= (0 hrs/wk) to 8= (more than 6 hrs/wk).	3.024	2.382	(1.5-2.0 hrs)	2.741	2.065	(1.5-2.0)

Note. "L" is the interval level that the mean and standard deviation represents.

Contrary to what was predicted, Pearson *r* analysis revealed that long work hours did not have a negative effect on academic performance. However, results did confirm the prediction that employment may detract from the amount of time spent in school related clubs and athletics ($r= -.35$, $p=.00$). In general, both male and female employed students who worked more than 10 hours per week, were less involved in school activities when compared to students who worked less than 10 hours per week or who were not employed.

DISCUSSION

As is indicated by conflicting results of previous research, working while in school proves to be a controversial issue. Contrary to the hypothesis that students who worked more than 20 hours per week have a low GPA, spend little time on homework daily, and cut-class frequently- all academic performance results for both male and female participants of the proposed study were not significant. However, a significant negative correlation was found between student employment and amount of involvement on school extracurricular activities. Specifically, the more the college student worked, the less time he or she was able to devote to school clubs, meetings, or athletics.

The number of hours worked per week was unrelated to grades obtained. How were students working long hours (i.e. over 20 hours per week) able to maintain their high grade point averages? There are several possible explanations. One common strategy employed by students is simply choosing easier professors, classes, or lighter class loads in general (McNeil, 1984; Steinberg & Dornbusch, 1991). Another possible strategy is that the participants may have made better use of the small amounts of time they did have available during each day (Hammes & Haller, 1983).

A maintained GPA could also be explained by the personality of the student worker. Perhaps the better student is conscientious and determined to do well; therefore, capable of taking on greater responsibilities. This may explain why the participants of the proposed study , who were initially good students (mean GPA= 3.1-3.5), were able to maintain their high GPA while working.

A negative correlation between work hours and amount of time in school related activities exists. Though no causal relationship can be drawn from this correlation, there is a possible explanation for the relationship between employment and involvement in school activities. Perhaps participants who worked long hours chose to spend their free time in academic pursuits (i.e. studying: thus, a high GPA), fearing extra time spent in school activities may jeopardize their grades.

Prior research has found working to be negatively associated with not only school involvement (Steinberg & Dornbusch, 1991), but also greater psychological distress (Greenberger, Steinberg & Vaux, 1981) and higher rates of drug use and delinquency (Steinberg & Dornbusch, 1991). Additional research is needed in these areas investigating any possible gender or racial differences. College is becoming an increasing financial burden on many college students. For many students who wish to continue their education, working is no longer an option, it is a necessity. Living in a world of yearly increasing tuition rates, forcing more students into the workplace, continued research on the effects of employment on college students' academic performance, psychological and social well-being would be directly beneficial.

Gender Differences In Coping Strategies And Cardiovascular Responses To Stress

Eric Shaw and Foye Smith

Department of Psychology
Morehouse College
830 Westview Dr. S.W.
Atlanta, GA 30314

Faculty Advisor:

Vernessa R. Clark

The study investigated gender differences in hostility and perceived stress. Heart rate and blood pressure measurements were taken while participants viewed two racist scenes on videotape. One racist scene depicted an African American soldier being discriminated against, by another African American, because of his race. The other scene depicted an African American being discriminated against by Caucasians. Afterwards the Cook and Medley Hostility Scale and the Perceived Stress Scale were administered. A t-test was used to detect differences in cardiovascular reactivity between males and females. Significant differences in perceived stress scores were found, females scoring higher than males. With heart rate, females had higher reactivity than males in response to the white on black racist scene. Females also had higher diastolic blood pressure than males for the black on black scene. This study will help identify who is most susceptible to stress related diseases.

INTRODUCTION

Coping as a definition has changed from being as simple as a response to emotions to as complex as cognitive processes (Folkman & Lazarus, 1988). The focus has also changed to include information concerning the effectiveness of coping styles, validated through measures of cardiovascular reactivity, in response to an induced stressor. Assessing coping in blacks require a new diagnostic system that includes stress caused by racism and to account for differences in gender. Coping styles used must also be accounted for in understanding the linkage of personality, gender and cardiovascular responses (Harrell, 1979).

Hostility

Hostility is defined as a personality construct seen in people who are easily angered, have high levels of resentment and irritability, and are cynical and mistrusting of others (Smith & Frohm, 1990). This construct, which is more prevalent in males than females, is associated with high levels of systolic and diastolic blood pressure (Anderson, Meyers, Pickering & Jackson, 1989).

Perceived Stress

Perceived stress refers to the degree to which situations in one's life are appraised as stressful (Cohen, Kamarck & Mermelstein, 1983). An important part of this view is that the response is not based solely on the intensity or any other particular quality of the event, but rather is dependent on personal and contextual factors as well (Cohen et al., 1983). Cohen et al.,(1983) found that females have higher levels of perceived stress than males.

The present study examined gender differences in coping strategies and cardiovascular reactivity. It was hypothesized that males would score higher on the hostility scale and perceived stress scale. It was also hypothesized that males would have greater cardiovascular responses to stress.

METHOD

Participants

Twenty females and twenty males participated in the study. The students were between the ages of 18-26 and were screened for cardiovascular disorders.

Apparatuses

Prior to the experiment, each individual was given a screening form and an informed consent form. The screening form identified medical conditions that excluded the individual from participating in the study. The informed consent form was administered after an explanation of the nature of the study was given. The Cook and Medley Hostility Scale (Cook & Medley, 1954) - a measure of hostility, and the Perceived Stress Scale (Cohen et al., 1983) - a measure of stress were used.

The NCCOM3 impedance cardiograph and microcomputer system were used to assess heart rate. To obtain these measures, eight electrodes were placed on the neck and both sides of the body near the area of the xiphisternum. Blood pressure was taken by the Ohmeda Fina Pres Model 2300 blood pressure monitor. The psychological stressors used in the experiment were two racist scenes and one neutral scene on videotape. One of the racist scenes depicted black students being harassed by white students (white on black scene). The other racist scene depicted a black soldier of higher rank harassing another black soldier of lesser rank because of his race (black on black scene). The neutral scene, which served as a control, depicted a rabbit running in a field at sunset.

Procedure

Upon entrance of the laboratory, each participant was given a screening form and an informed consent form and two personality questionnaires. The two personality questionnaires were the Cook and Medley Hostility Scale a measure of hostility and the Perceived Stress Scale a measure of stress. After all questions were answered, the recording equipment was attached. After the presentation of each scene, the participants were asked to reflect on what they saw. They were asked to put themselves in the position of the victim and speak to the authority figure. Heart rate and blood pressure were measured before, during and after each scene.

Scoring of Physiological Measures

Measurements of heart rate and blood pressure were taken prior to the stimulus (pre-stimulus period), during the stimulus (stimulus period), while the subject reflected on the stimulus (reflection period), and while the subject recovered from the stimulus (post stimulus period). Each period lasted eighty seconds and measurements were taken every twenty seconds. The averages of the measurements were used in the analyses.

RESULTS

T-test analyses were used to analyze gender differences in hostility, perceived stress and cardiovascular responses to the racist stressors. Hypothesis #1 (that males will score higher on the Cook and Medley Hostility Scale) was not supported. Hypothesis #2 (that males will score higher on the Perceived Stress Scale) was not supported. Females ($\bar{x}$=26.9), had higher perceived stress scores than males ($\bar{x}$=21.1), $t(39)=2.59$, $p=.014$. Hypothesis #3 (males will have greater cardiovascular responses to the racist stressor) also was not supported. Females had higher heart rates ($\bar{x}$=83.8), than males (71.9), $t(40)=5.54$, $p=.000$ and higher diastolic blood pressure (females $\bar{x}$=77.2, males $\bar{x}$=69.9), $t(37)=2.00$, $p=.053$ during the white on black racist scene. In addition females, ($\bar{x}$=84), had higher heart rates than males ($\bar{x}$=67.7), $t(40)=4.92$, $p=.000$ during the black on black racist scene.

T-test analyses were also performed on the difference between the pre stimulus and stimulus period between the genders. Although not significant, females had greater systolic blood pressure differences between the pre stimulus and stimulus periods for both scenes. Females also had greater diastolic blood pressure differences between these periods. These t-values approached significance with a probability level of $p=.07$ and $p=.068$, respectively.

DISCUSSION

The results of the study did not support the hypotheses presented. There was no significant difference in systolic blood pressure, between males and females, for the white on black scene. Females also had higher diastolic blood pressure for the black on black scene.

This finding was supported by Baum and Grunburg (1991) who reported that women had heightened hypothalamic pituitary adrenal activity during stress due to hormonal disregulation. Lastly women had higher levels of perceived stress. This finding indicates that women perceive the events in their lives as more stressful than men (Cohen et al., 1983). They also have greater cardiovascular responses to these stressful events. Further investigation of these variables is warranted.

Table 1
Mean Gender Differences In Perceived Stress and Cardiovascular Reactivity

	Perceived Stress	Heart Rate Stim (white on black)	Heart Rate Stim (black on black)	Diastolic Stim (white on black)	Systolic Diff (scores for both scenes)	Systolic Diff (black on black)
Males	21.1	71.9 b/m	67.7 b/m	69.9 b/m	2.7 mm/Hg	51.2 mm/Hg
Females	26.9	83.8 b/m	84 b/m	77.2 b/m	10.05 mm/Hg	43.9 mm/Hg
T-values	*t*(37)=2.6 *p*=.014	*t*(38)=5.5 *p*=.000	*t*(38)=4.9 *p*=.000	*t*(35)=2.0 *p*=.053	*t*(35)=1.8 *p*=.070	*t*(36)=1.3 *p*=.068

Legend
Diff - Differences between pre-stimulus and stimulus period
Stim - Stimulus period
b/m - Beats per minute
mm/Hg - Millimeters of mercury

An Extension of the "Two-Baskets' Theory of Self-Cognitions to Native Americans

Mandy D Smith

Department of Psychology
New Mexico State University
P O Box 30001, Dept 3452
Las Cruces, NM 88003-8001

Faculty Advisor

David Trafimow

A theory that private and collective self-cognitions are stored in separate locations in memory (Trafimow, Triandis, & Goto, 1991, Trafimow, Silverman, Fun & Law, 1997) was tested with a sample of participants (Native Americans) that differed substantially from those used in previous research Nevertheless, the obtained findings were similar to previous ones, and supported the generality of the theory

INTRODUCTION

Several researchers (e g , Greenwald and Pratkanis, 1984, Triandis, 1989) have distinguished between private and collective aspects of the self, and have argued (Triandis, 1989, 1994) that people from individualistic cultures emphasize private aspects of the self, while those from collectivistic cultures emphasize collective aspects of the self Further, much evidence supports this distinction For example, when individualists and collectivists are asked to complete the Kuhn and McPartland self-attitudes instrument (a series of statements beginning with "I am"), individualists tend to write down more private self-cognitions (statements about traits, states, behaviors) and fewer collective self-cognitions (statements about group membership or common fate) than do collectivists (Bochner, 1994, Triandis, McCusker, & Hui, 1990) However, knowing that culture affects which aspects of the self are emphasized does not, by itself, explain how self-cognitions are organized

To answer this question, Trafimow, Triandis, and Goto (1991) suggested two possible ways of accounting for the findings described below First, self-cognitions could be stored in one location in memory (the "one-basket" theory), but with culture affecting the relative number of private versus collective self-cognitions stored there Invididualists have more private self-cognitions and fewer collective self-cognitions stored in memory than do collectivists, and consequently, this is reflected in the number of private and collective responses they make to the "I am" instrument

Second, private self-cognitions could be organized around a more general private self-concept and collective self-cognitions around a more general collective self-concept (the "two-baskets" theory) However, culture affects the relative accessibility of these self-concepts Thus, for individualists, the private self-concept, and hence, the private self-cognitions associated with that self-concept, are more accessible than for collectivists The reverse is true regarding the collective self-concept and the collective self-cognitions associated with it

Trafimow et al (1991) distinguished between these two theories in two ways First, they pointed out that according to the two-baskets theory, it should be possible to prime the private self, and facilitate the retrieval of private self-cognitions, or to prime the collective self, and facilitate the retrieval of collective self-cognitions According to the one-basket theory, there is only one "self", and so attempting to prime different "selves" should result in a failure Second, Trafimow et al suggested that according to the two-baskets theory, the order in which people write down self-cognitions should be a function of the self-structures from which they are retrieved If a private self-cognition is retrieved, then the private self-concept is presumably accessible, and the next item retrieved should be another private self-cognition Similarly, if a collective self-cognition is retrieved, then this indicates that the collective self is relatively accessible, and the next item retrieved should be another collective self-cognition According to the one-basket theory, there is

BEST COPY AVAILABLE

no reason to make this prediction. Both of the predictions made by the two-baskets theory were confirmed, and these findings were later replicated by Trafimow, Silverman, Fan, and Law (1997).

Despite a variety of findings that have supported the theory (see Trafimow, 1997 for a review), one weakness of the theory is that the majority of the research was performed with student samples obtained from the United States (but see Trafimow et al., 1997 for a student sample obtained from Hong Kong). Given that Amir and Sharon (1987) found that most findings fail to generalize across cultures, this is a serious limitation for a supposedly "general" theory. Consequently, our goal was to test the generality of the theory by using a sample of participants from a population that is rarely studied in general, and has never (to our knowledge) been studied by researchers who have investigated the cognitive structure of self-cognitions.

EXPERIMENTAL METHODS

Participants

Twenty-eight male and 34 female Native Americans volunteered to participate in the experiment, and were randomly assigned to the conditions described below. Unlike previous samples, over 41% of this sample was over 30 years of age. Furthermore, 93% reported having spent a significant portion of their life on a reservation.

Procedure

The procedure was similar to that used by Trafimow et al. (1991, Experiment 2). Subjects read a story about an ancient Assyrian named Sostoras who had to send troops to help Sargon I in conquering Mesopotamia. Sostoras also had to assign someone to lead the troops. The priming manipulation was embedded in this story. Participants learned that Sostoras had assigned Tiglath who was a "member of his family" (collective self-prime) or a "talented general" (private self-prime). In addition, and in contrast to Trafimow et al. (1991), there were also control participants who were not primed. Later on, as part of an ostensibly separate experiment, they were given 5 minutes to complete the Kuhn and McPartland (1954) self-attitudes (20 "I am" items) instrument.

RESULTS

The results were analyzed as a 3 X 2 mixed factorial with Prime (private self-prime vs. collective self-prime vs. no prime) as the between-participants factor and Item type (private self-cognition or collective self-cognition) as the within-participants factor. A few of the items were also coded as "allocentric", but were not included in the subsequent analyses (see Triandis, 1989, Trafimow et al., 1991).

There was a significant within-subjects main effect for response type, *F*(1,58) = 80.33, *p*< .001. Consistent with other findings (e.g., Trafimow et al., 1991; 1997), there was a greater proportion of private self-cognitions than collective self-cognitions retrieved (*M*= .69 and *M*= .26, because a few items were allocentric, these do not sum to 1). Furthermore, the proportion of collective self-cognitions was greater than that obtained from the U.S. college student sample used by Trafimow et al. (1991, Experiments 1 and 2) (*M*= .26 versus *M*= .13 and *M*= .15, *p*< .05 in both cases), and similar to the student sample obtained by Trafimow et al. (1997) from Hong Kong (*M*= .26 versus *M*= .26), thereby suggesting, along with Bahr, Chadwick, and Day (1972), that Native Americans are more collectivistic than traditional U.S. students. More importantly, however, the Item type main effect was moderated by a Prime X Item type interaction, *F*(3,58) = 3.45, *p*< .05. Participants who received the collective self-prime or no prime retrieved more collective self-cognitions than did those who received the private-self prime (*M*= .29 and *M*= .32 versus *M*= .18), and participants who received the private self-prime retrieved more private self-cognitions than did participants who received the collective self-prime or no prime (*M*= .77 versus *M*= .64 and *M*= .65). Cell comparisons confirmed that the collective self-prime resulted in findings that were similar to the no prime condition with regard to both private and collective self-cognitions (*p*> .1 in all cases), and that the private self-prime resulted in findings that were different (*p*< .05 in all cases). Finally, to ensure that the no prime control group was not responsible for the Prime X Item type interaction, this group was dropped and a new analysis was conducted. Consistent with the two-baskets theory, this analysis also resulted in a significant interaction, *F*(1,39) = 5.26, *p*< .05.

Conditional probabilities were also analyzed. The probability of retrieving a collective self-cognition was greater following the retrieval of another collective self-cognition than following the retrieval of a private self-cognition (*M*= .35 versus *M*= .19),

$p < .05$, and the probability of retrieving a private self-cognition was greater following the retrieval of another private self-cognition than following the retrieval of a collective self-cognition ($M = .76$ versus $M = .60$), $p < .05$. Thus, like the previous analyses, the conditional probabilities are consistent with the two-baskets theory.

DISCUSSION

The data strongly supported the generality of the two-baskets theory to a Native American population. The data are particularly impressive given research by Amir and Sharon (1987) who found that most experimental manipulations fail to generalize across cultures. Further, the experiment was consistent with a viewpoint expressed by Pepitone and Triandis (1987) that "... the more exotic the cultural sample, the more general the original hypothesis that predicted the results" (p. 472). However, there was one unexpected aspect of the data. Trafimow et al. (1997) had included a "no prime" control group in their study using participants from Hong Kong, and found that the private self-prime resulted in findings similar to the no prime control group while the collective self-prime resulted in different ones. Here the reverse was true--it was the collective self-prime that resulted in findings similar to the no prime group and the private self-prime that differed. These results suggest that although the implications of the two-baskets theory generalize across diverse cultures, findings not specifically predicted by the theory (e.g., which prime should be most different from a no prime control group) may not. More generally, the present article demonstrates the importance of cross-cultural comparisons for testing theories.

The Relationship Between Self-Esteem and Extraversion

Wendy S. Peterson

Faculty Advisor:
Dr. Cynthia Crown

Past research has indicated that self-esteem is positively correlated with extraversion when examined with other variables such as shyness, social participation, anxiety, loneliness, social participation, self-monitoring, coping, and baldness. The present study hypothesized that self-esteem and extraversion would uphold the finding of past research. Thirty-seven undergraduate students participated in the study by completing the Coopersmith's Self-Esteem Inventory and the Keirsey Temperament Sorter. A correlation coefficient was computed and failed to indicate a significant correlation between the variables. It might be that study had too few participants to demonstrate an effect.

BACKGROUND

In the last fifteen years much research has been conducted on the personality dimensions of self-esteem and extraversion, however most research has combined these two variables along with other aspects of personality (e.g. loneliness, shyness, coping, social participation, and baldness).

The relationship between self-esteem and extraversion has given researchers insight into social aspects. When self-esteem and extraversion were studied by Kameth and Kanekar (1993) with respect to men and women, it was found that women were more likely to have low self-esteem and to be less extraverted than men. However, research has not always consistently supported this finding (Kawash, 1982).

Current social concerns revolve around anxiety, shyness, loneliness because of the individualistic culture we have. Researcher have been recently studying the relationships among these concerns, self-esteem, and extraversion. With respect to anxiety, it was found that self-esteem consistently correlated with low anxiety and with high extraversion with both males and females (Kawash, 1982; DeMan and Efraim, 1987). Kawash also discovered that since low anxiety and high extraversion were source traits, overt behaviors, it might be that these source traits led to positive self-esteem which was identified as a surface trait. Shyness was found to correlate with low self-esteem and low extraversion. Bennett and Lawrence (1993) found three results when studying inherent and situational shyness. These results supported past research findings in three areas: 1) different types of shyness existed, 2) that there was a significant relationship between low levels of shyness and high levels of self-esteem, and 3) shy individuals tended to be more introverted (Lawrence and Bennett, 1992). Hojat (1983) studied loneliness with respect to self-esteem and extraversion and found that loneliness was negatively correlated to both self-esteem and extraversion.

Studying loneliness, anxiety and shyness offers us information about the people of our society. What is just as important is how these people deal with aspects of their lives. Ways that researchers have observed are social participation, self-monitoring, and seeking social support. DeMan and Efraim (1987) found that extraversion was the single best predictor of social participation. They also found that extraverts tended to report higher self-esteem, but that it was not significantly related to social participation. When people are involved in social participation, self-monitoring is an coping aspect that many people use without realizing it. It was found that high self-monitoring was positively correlated with extraversion and self-esteem. Therefore, the higher one's self-esteem and extraversion, the better the person is at attuning their self-presentation and adjusting it to adhere to the expected behavior of others (Briggs et al., 1980). Seeking social support, when studied by Amirkhan, Risinger, and Swickert (1995), was found to positively correlate with self-esteem and extraversion.

The previous studies mentioned have examined many personality traits and ways of coping. Wells, Willmoth, and Russell (1995) researched physical aspects that they hypothesized had an influence on self-esteem and extraversion. With respect to baldness they hypothesized that a person who had low self-esteem and felt unattractive compounded with baldness at an early age would lead to social withdraw. Results indicated that "hair loss in males was associated with depression, low self-esteem, neuroticism, introversion and feelings of unattractiveness, independently of age; and in the case of self-esteem , introversion, and feelings of unattractiveness, the effect was especially pronounced in younger males" (Well et al., 1995, p. 343).

While self-esteem and extraversion influence many other factors, do they influence each other? The present study aims to examine and discover a relationship between self-esteem and extraversion and support previous research that has indicated a consistent positive correlation between self-esteem and extraversion.

METHOD

Participants

Thirty-seven undergraduates from Xavier University in Cincinnati, Ohio, were recruited to participate in the study. The sample included 10 males and 27 females, most between the ages of 18 and 21 with one participant of the age of 60. A portion of the participants were recruited from a general psychology course in which they received credit for participating. Other participants were undergraduates gathered from various pars of campus. Ethical guidelines of the American Psychological Association were followed. Each of the participants were given a consent from which they filled out before completing the survey.

Materials

The Coopersmith Self-Esteem Inventory (SEI; 1987) was used to measure self-esteem. The second instrument used was the Keirsey Temperament Sorter (KTS) which measured extraversion. This survey consisted of 70 questions of which only 10 related to extraversion. Therefore, only questions relating to extraversion were used. The KTS has been used instead of the Meyers Briggs Indicator when money and time are a crucial factor. Due to my limited funding and time constraint, I chose to use the Keirsey Temperament Sorter because it was free and easy to score.

The first two groups that completed the survey wee gathered from a general psychology course. These students met in a room to take the surveys on two different days at the same time. Other undergraduates students were asked to complete the survey on a one to one basis with the experimenter. The other undergraduate students were recruited from personal acquaintances and other undergraduates students who were unknown to the experimenter. The unfamiliar students were asked to volunteer in the Down Under of the University Center of Xavier University.

All participants were given a manilla folder with two consent forms and the Coopersmith SEI and the KTS. The participants were asked to fill out both consent forms. Then one consent form was collected by the experimenter and the other consent form was kept by the participant for his or her records. After the consent forms were completed the participants filled out the surveys. The Coopersmith's SEI asked for the participant's name, institution, occupation, age, gender, and date. The name, institution, and occupation slots were whited out to keep responses confidential. Age and gender were assessed so the demographics could be properly reported. When the surveys were completed, they were placed in a single manilla folder. All responses were kept confidential, because participant identification numbers were used. The scales were later scored by the experimenter and keyed into the SPSS program.

RESULTS

Thirty-seven surveys were completed and the results were computed. The means and standard deviations for self-esteem and extraversion are presented in Table 1. Correlations between the variables are presented in Table 2. Inspection of Table 2 indicates that there were no significant correlations.

Table 1: Means and Standard Deviations for Self-Esteem and Extraversion

Variables	Mean	Standard Deviation
Self-Esteem	74.11	19.95
Extraversion	06.05	02.01

Table 2: Correlations Between Self-Esteem and Extraversion

Variables	Self-Esteem	Extraversion
Self-Esteem	1.00	.13
Extraversion		1.00

DISCUSSION

The results failed to indicate a significant correlation between self-esteem and extraversion despite past research that supported a positive correlation.

There are several possible reasons why significant results were not found. The lack of significance may have resulted because of the sample size. Only 37 participants were involved in this experiment compared to the hundreds used in previous studies. The small number of participants may not have been sufficient enough to show the actual correlation between self-esteem and extraversion. Another possible explanation may have been the haphazard way in which the participants were recruited. Part of the sample was recruited from a general psychology class which had a requirement to participate in experiments. Other participants were recruited from places on campus.

One last shortcoming of the experiment may have been the Keirsey Temperament Sorter. Reliability and validity were unavailable for this test, and, therefore, this test may have been an unreliable test for the population sample despite widespread usage of the test by school counselors.

Future research concerning self-esteem and extraversion should build upon the study conducted by Kawash (1982). Self-esteem was defined as a surface trait and extraversion was defined as a source trait. Since extraversion is a source trait of personality, does it affect surface traits such as self-esteem?

In conclusion, future research should continue to study the relationship between self-esteem and extraversion. Further studies should manipulate self-esteem as an independent variable and observe any effects it would have on extraversion. Findings from an experimental study may help clinicians when dealing with lonely, anxious, or depressed patients.

Seaside, California 93955-8001

Dr. Ruben Mendoza
Dr. Manuel Carlos

Chicano gangs have been a social phenomenon in California since the early 1940's. Each gang has idiosyncratic characteristics such as history, size, amount of criminal activity, and structure. This paper examines the internal dynamics, command structure, and organizational principles of teenage and adult Chicano gangs. The focus is a case study of a specific population in a mid-size California county. The paper examines the rules which govern the hierarchy of officers and "foot soldiers". The working hypothesis is that gangs are a reflection of the marginalized status of the Chicano population in urban settings. Study is based on original work gathered by the author from personal interviews, observations, and questionnaire's.

BACKGROUND

For the purpose of this ethnographic study, the generic term "Chicano" will be used to describe the gangs studied. Other terms used by researchers and the population studied are: Mexican American, Hispanic, Latino, as well as Chicano. There are many definitions used to define gangs. In this research, gangs are defined as:

> A self-formed association of peers, bound together by the mutual interest, with identifiable leadership, well defined lines of authority, and other organizational features which act in concert to achieve a specific purpose which generally but not exclusively, conduct illegal activities and control over a particular territory, facility, or type of enterprise.

Gangs have been a constant part of United States history since the early 1840"s. Marginalized youth who immigrated Europe, formed brotherhoods for protection and survival. They were much like the gangs of today with minor differences. Turn of the century gangs used and sold morphine while gangs today market crack and cocaine. Earlier gangs used knives while guns are more prevalent in modern times. Historically, gangs were found in cities with large ghettos and minority populations such as Los Angeles, Chicago, and New York. In the 1990's, gangs can be found in all fifty states and in cities of any size. However, the factors which led to the formation of Irish gangs in the 1840's, are indeed similar to the situations which gave rise to the Chicano gang movement of the 1940's.

Chicano gangs share common features including a high sense of territorial ownership and pride. Loyalty and trust are at the core of the Chicano gangs. There is a strong sense of historical roots that both bind and divide the gangs. These roots have provided the strength and staying power over the years to gangs as well as the weakness. History accounts for the desire to revive the La Raza as well as the hesitation to join forces.

In several works, Joan Moore has stated that Chicano gangs did not exist prior to 1942. Before that time, Mexican American youth formed social clubs where they would drink and dance together. The Sleepy

Lagoon trial and the "Zoot Suit Riots" resulted in the formation of the first Chicano street gang, the White Fence. White Fence was formed as a means of protecting the barrios from outsiders as well as self defense and to restore lost pride and respect.According to Mirande (1987, 172):

> The beating and stripping of the zoot-suiters were, thus, attacks not only on their culture but also their manhood. The pachuco was left bleeding and naked stripped of his masculinity or machismo.

A historical overview is essential to the understanding of the formation of Chicano gangs in California. World War II was a catalyst that mobilized anglo citizens in southern California. There was a need to have a "common enemy" among the anglo population. With the Japanese in interment camps, the Mexican was the logical target. It was unimportant that the Mexican American soldiers were the most decorated fighters of all minority soldiers. In the battlefield, they had been first class citizens..on the streets, they were viewed as the enemy.

In 1942, there were several large military installations in the Los Angeles area which placed approximately 50,000 servicemen on the streets every weekend. The United States was at war, tension was high, and tempers flared. On August 1, 1942, a Mexican male was found dead in a mud ditch near the Sleepy Lagoon reservoir. The following day, twenty-two boys from the 38th. Street barrio were arrested for murder. The men were kept in jail and beaten over a period of three months. When brought to trial, they were denied haircuts and a change of clothing because, "the appearance of the defendants is distinctive, their style of haircut, the ducktail comb, the pachuco pants and things of that kind were important evidence." (Endore 1944, p. 31).

During the trial, the sheriff, a self proclaimed anthropologist testified as to the "biological killer instinct of the Mexican because of his Aztec roots" and urged that the whole gang be sent away to prison. The media played up the bloody thirsty nature of the Mexican population by issuing warnings to the public. The end result was the conviction of all twenty-two young men for murder and their incarceration at San Quintin Prison. The men spent eight months in prison before a federal misconduct investigation appeal set them free.

The barrio became a battlefield on weekends. Groups of servicemen would cruise the streets looking for zoot suitors. Young men were dragged out of bars and movie houses by anglo soldiers. Mothers and girlfriends watched in horror as the men were beaten, stripped of their clothing and left bleeding in the streets. To add insult to injury, the police would follow behind and arrest the victims rather than the perpetrators. Hundreds of Mexican American youth were arrested. Newspapers continued to warn that the Mexican was "not to be trusted because of their thirst for blood stemming from a heritage of cannibalism and human sacrifice.." The humiliation suffered by the young men in the barrio and their treatment by the authorities only intensified their distrust of the law. It also served to strengthen the common roots shared by the community as gangs and cliques flourished as a mode of protection and survival.

FINDINGS

According to the Gang Suppression Task Force in the California county studied, there are 31 Chicano street gangs with a membership of more than 3,500. This number does not include the "wanabe" members. These gangs or cliques pledge allegiance to either the Nortenos, Surenos, or Border Brothers.

Northern gang members claim the color red and the number 14, for "N". The letter also refers to Nuestra Familia, the prison gang with northern street ties. The average age of the northern street member is 13 to 25 with a few veterans as old as 45. In the prison system, the average age is 26. Black gang members and northern prison gangs are allies in time of need.

The NF structure is dictated by a very elaborate and strict written constitution. The gang takes priority over everything else in the members life, including family. The NF is selective in its recruiting. They usually only recruit Chicanos from northern California. Members with mixed blood find it hard to move up in rank if they are less than 50% Chicano. The NF attempts to shy away from elementary schools. One Lieutenant informed me that:

> We (NF) are very worried about the children. They have no idea what they are doing out on the streets. They don't know who they are. They wear the colors and flash the sign but know nothing of the history. They are willing to die for a color and they don't even know why..they are breakin all the rules with their gang banging.. they are suppose to protect the innocent..I don't blame them. There is nobody out there to teach them the ways. I had my uncle who schooled me and then gave me the power. Who do they have? They don't even have heroes. I had Chavez..who do they identify with? They need to get back to the business of education. We (NF) want them educated. We need doctors, lawyers, accountants, and teachers for the barrios helping the people, the brotherhood, themselves. They should forget about the gangs until they know what they are doing and why. Banging is a liability to the brotherhood, not a help. This is why a green light was given by the shot caller.

The NF is encouraging its young people to stay in school and get an education. Most NF members in prison are engaged in a GED program or a college education program.

The NF has 24 bonds that a man must take to climb the ladder. Officers are not allowed to use drugs and must keep both body and mind in top physical form. Most speak only English, a few are bilingual and many are third or fourth generation members by way of "passing the power." Northern gang members are often referred to as "Farmers" by their southern counterpart.

Southern gang members claim the color blue and the number 13 for the letter "M" which refers to its prison counterpart Mexican Mafia or EME. The Mexikanemi or "soldiers of Aztlan" is much like a military operation. The average age of southern street members is 11 to 23 with a few veterans in their late 20's or early thirties. In the prison system, the average age is 24. In times of trouble, the white prison population and the southern gangs form an alliance against the Northern gangs and the blacks.

In the southern structure of EME, the president is in charge of the system with the assistance of a vice president. Generals have regional authority while lieutenants control units and sergeants control the soldiers and associates. One EME officer informed me that, "The streets are the recruiting grounds. Schools, parks, it don't matter, we make them members. Got little babies packin.." This same spokesman admitted that if a young person is lucky, he never gets caught and does not enter the judicial system. If he does end up in a juvenile facility, soldiers are standing by begin his training which will continue on into the adult system. The EME has a saying, "respect the strong, use the weak." Southerners are referred to as "scraps" and "Wetbacks" by northern members.

Both groups have common factors despite the differences. Both use a matrix system of writing when they need to insure that the wrong people are not able to decode the message. The system is updated on a regular bases. Both groups use placas to mark their territory or boundaries. They are all highly territorial and this has lead to recent problems. In the past, boundaries were clearly marked by streets. With population growth, a mobile and migrating society, areas become questionable. Gang members now meet and party in cross areas where the potential for conflict and violence are greatest.

Most street gang members interviewed, north and south, indicated that the joining ritual was the same. New or potential members are "jumped in". They have to be beaten up by members of the gang and take the beating in order to join. The degree of violence used in the ritual depends on if you are barrio or non barrio. Getting the gangs tattoo is also a sign of toughness and commitment.

Prison is somewhat different. When an inmate arrives, someone has to sponsor him. The landlord will send someone to check out his papers and he has to prove himself. If something goes wrong, the member that sponsored him, has to take care of the problem. There is an imaginary line in prison gangs. If one is allowed to step over the line, he can never go back. It is a lifetime commitment of 24-7. The only way out is death. These groups pledge their lives to the family and put the cause above all else. Many are doing life sentences but still call the shots from behind the walls.

According to the California Department of Justice, in 1992, there were 1,272 validated gang members in the correction system. Validated members are automatically assigned to Pelican Bay SHU facility at a cost of $20,730 a year. That same year, there were 5,098 gang members in the youth authority at a cost of $31,370 per year.

Pelican Bay is an ultra modern facility located on the Oregon border. It has been called the Alcatraz of the 90's. A person serving a life sentence without possibility of parole may be placed in general population and be afforded human contact while a validated gang member in for petty theft is placed in the SHU or secure housing unit. The SHU unit is suppose to eliminate gang communication and operation. Inmates are kept in their cells 23 hours a day and are only out for a shower or a workout in the dog yard. There are no windows in the SHU cells and the doors are solid with pinpoint holes. Still, the inmates do find very effective modes of communication and always know what is going on.

The structure of the gangs are the same. The dynamics of membership is divided along the following lines:

Core Members are the leaders and regulars of the inner clique involved with the day to day operation of the gang. They set the standards, recruit, and set the tone of the groups behavior. The more hard core the core members, the more violent the group will be.

Associate and Peripheral Members have a lower status and may hold alliance to one particular core member. They do not see themselves as being an important part of the group.

Floaters have a very high status. They are articulate, resourceful, and know where to go and who to see to get things done. They are often used in peace talks and negotiations with rival gangs. For example, one floater was called upon by prison officials during this research to end fighting between the north and south which had resulted in a shooting and several stabbings. The problem was the number of days that each group had in the yard. The floater was able to work out a fair and equal number of days for each side to use the yard and future trouble was avoided.

Wanabes and Recruits are the younger, aspiring or potential members of the gang. This group can also be the most dangerous because their reasoning ability is not fully developed and they have a need to prove themselves.

O.G. or Veterans are usually in their mid 20's and have already devoted years of their life to the gang and survived. They are usually not as visual or as active. Those in jail are symbols and still have considerable influence.

Why join a gang? When ask. most street gang members and prison gang members gave the same or similar reasons. All those interviewed listed protection as a major factor. Identity was the second most common reason for joining a gang. Many felt alienated from the community that they lived in. They felt as if they were being discriminated against in school, by law enforcement, and society as a whole. One young man stated that the "teachers did not expect me to do much of anything but join a gang and drop out of school, so that's what I did." Many were searching for a sense of family or belonging. What they could not get at home from parents, they found on the streets in brotherhood. Not all, but a large number of those interviewed came from divorced or single parent homes. One common thread found in all interviews and in the questionnaires was the quest for love and acceptance.

Another factor in gang membership was economic survival. Many young people indicated that they had turned to gang life as a means of earning a living. Chicano youth from disenfranchised neighborhoods characterized by overcrowding, high unemployment, high drop out rates, and lack of social and recreational outlets, are more likely to turn to gangs. More than 75% of the gang members studied did not have a high school diploma. Lack of education makes finding a job paying more than minimum wage almost impossible.

Perhaps the saddest fact of all was the sense of hopelessness. Many of the young men did not have dreams beyond the streets. Many indicated that they did not expect to live past forty. For all the bravo and tough faces shown by the prison gang members, it was obvious that self-esteem was extremely low and fear of living, not dying, very high. They had never had the experience of being told that they were an important and productive part of society. Somewhere along the line, someone failed to give these young men the coping skills and the self esteem needed to compete in a discriminating society that has the need to dominate. Where society failed, the brotherhood of the gangs were successful.

CONCLUSION

Studies indicate that gangs exist for multicausual reasons. Economics, political, law enforcement policy, and attitudes, as well as group identity all play a major role in the staying power of gangs. Gangs are not all bad. They exist to meet needs that are not being met elsewhere. All gang members are not from poor families. In the case of Chicano gangs, discrimination and marginal acceptance as well as protection play a major role in gang formation.

The existence of Chicano gangs can best be explained using the Colonization Theory and the Radical Theory. Quinnery stated it best when he wrote:

> Society is characterized by diversity, conflict, coercion, and change..rather than by consensus and stability..Law incorporates the interest of specific persons and groups; it is seldom the product of the whole society. Law is made by men, representing special interest, who have the power to translate their interest into public policy. Unlike the pluralistic conception of politics, law does not represent the diverse interest in society, but supports some interest at the expense of others (35).

Crime, deviance, and gangs are common among immigrants because they are often forced into poverty. Chicanos however, were a colonized group who did not immigrate. Instead they were forced in mass to accept the

867

American ideal. American society is a diverse racial-ethnic mix of groups that have not been integrated into a cohesive "melting pot" but rather is a society characterized by the subordination of some groups by others who benefit from their subordinate status.

To put this into perspective, Europeans came to the United States freely and as individuals while Mexicans were forced involuntarily en mass. The same thing happened in Ireland when it was colonized by the British. The result was the formation of the Irish Republican Army which is still fighting to this day.

Even though the Mexican colonized group came from a superior civilization, they still end up at the bottom of the socio-economic and political ladder. Their subordinate status makes for a cheap labor force. All the while, the dominate group strives to eradicate the language, customs, and heritage of the sub group. Diego Vigil discussed the insensitive education practices that often promote drop outs among the Chicano youth in several of his gang studies. Children need to feel appreciated and accepted as a valuable part of the society that they exist in. If they do not have their needs met by society, they will have them met on the streets.

According to Arnold Goldstein, the Radical Theory "goes far beyond mere matters of labeling, differential opportunity, or like concerns. Its target is no less than the social and economic structure of society."(17) Quinney explained the specific propositions of the theory from a sociopolitical thrust which when condensed states that crime and gangs are created by the wealthy who control the capitalist economy and make the laws. Laws are used by the elite class to subjugate the poor, minorities, and the weak. Government agencies are regulated by the government who represent the primary interest of the wealthy. Coercion is used because a capitalist society cannot exist without a subordinate class.

As long as the state of California chooses to validate gang members for tattoos and conversations change cannot occur. After parole, gang members hit the street and usually end up flipping burgers or washing dishes at minimum wage until the humiliation and frustration sets in and they break parole. More than 85% of the members in this study have been in and out of juvenile facilities and prison. Most of the population indicated that they would like to make a change but do not see it happening.

ACKNOWLEDGMENT

I would like to thank Charlotte Contreras for her assistance on this project. Special thanks to Dr. Ruben Mendoza who's insight, encouragement, and assistance made the project work. Respect and thanks to the men at the correctional facility who put aside their differences to sit down and share as a group and as individuals. Most importantly, thank you to my Aztecan Star for the support , guidance, and encouragement that allowed me to get the work done.

Faculty Advisor:
Maureen Vandermaas-Peeler

The purpose of this study was to examine the relationship between adolescent and parent values. Survey research was conducted to gather information regarding demographics and personal values from 30 parent-child dyads. Based on prior research, we hypothesized that: 1) parent and adolescent values would differ, 2) female adolescents' moral reasoning would be more similar to their parents' than their male counterparts, and 3) female and male adolescents' values would differ significantly. Use of Pearson's r and Analysis of Variance ($p < .05$) yielded results that supported the hypotheses. This indicates that parents are not the sole source of guidance in the process of value formation.

Young adolescents' attitudes and behaviors are often a reflection of their parents' beliefs. They are influenced by the words and actions of those individuals who have been responsible for them since their birth. However, as adolescents approach young adulthood, the values and morals they have grown up with are questioned. It is a time for the adolescent to grow in personal identity, think for him/herself, and take responsibility for his/her own actions (Marcia, 1966). The process of rethinking values and determining one's own beliefs should not be looked at as a rebellion, but rather a maturing process during which beliefs that guide our actions are formed (Miller, 1993).

These beliefs, which may also be referred to as a value system, are a cluster of an individuals' values (Kalven, 1982). Value systems include issues such as morals, values, and ideology. By contrast, a value is a single stable belief that guides our actions in any given situation (Miller, 1993). Values are also different from attitudes which cause an individual to view a given behavior in a favorable or unfavorable way (Kalven, 1982). While attitudes may change, values are generally more stable.

Why should values be studied? Values are necessary to gain membership in a social group. Different patterns of values are accepted by distinct groups, but acceptance of a groups' values are vital to gaining a place in a group (Werkmeister, 1967). Second, values affect the choices that we make. In today's world choices are abundant. Understanding how values are formed and transmitted allows a greater understanding of the factors affecting how choices are made and what different cultures value. Finally, the study of values, belief systems, and moral reasoning has a long history and has been explored from a variety of perspectives, one of which is psychological.

Modern psychological value theories have arisen from a developmental psychology perspective. The works of Kohlberg, Erikson, and Marcia are particularly important. Kohlberg's theory of moral development is based on the concept of internalization (Kohlberg, 1976). Internalization is the process of moving from external control of one's actions to internal control of one's actions. Though Kohlberg's levels of moral development are not tied strictly to specific age levels, it is likely that adolescents would be in level two, conventional reasoning. Within this level are two stages: interpersonal norms and social system morality. Interpersonal norms, stage three, is characterized by placing value on trust, caring, and loyalty; children in this stage often accept the belief systems of their parents. During stage four, social system morality, values are based on understanding of the social

869

BEST COPY AVAILABLE

order, law, justice, and duty (Kohlberg, 1976). These two stages of level two characterize the changes that begin in adolescence as individuals mature. During stage three, adolescents still accept the belief systems of their parents, but as they move into stage four, adolescents may begin to compare their parents' beliefs with the values and belief systems set up by those outside of their family group.

The work of Erikson is also important in understanding what happens during adolescence. In Erikson's theory of psychosocial development, each stage of our lives has a conflict particular to it. During adolescence, we face the identity versus identity confusion crisis (Erikson, 1968). While in this crisis adolescents begin to think about future plans and goals. This stage requires the adolescent to make many choices about his/her identity, including the development of a value system.

A third influential contributor to the understanding of development during adolescence, Marcia, who elaborated on Erikson's theory. Marcia (1966) determined four identity statuses -- diffusion, foreclosure, moratorium, and achievement -- that were the result of differing levels of exploration and commitment. These stages require varying levels of exploration and commitment, and though a better outcome can be fostered by supportive parenting that allows the adolescent the freedom to determine his/her own identity, in the end it is a responsibility that belongs to the adolescent.

These three theories concerning the developmental tasks of adolescence lend themselves to the typical script that is pervasive in our society concerning adolescent-parent relations. As children enter adolescence, they are compliant and tend to share their parents' values. As adolescents mature, however, conflict arises as their individual identities emerge. During this time, a process of self-exploration and value formation begins which eventually results in the crystallization of the adolescent's individual belief system.

Although a difference in beliefs between adolescents and their parents is often evident, under some circumstances parents do influence the beliefs and values of their adolescent children. Female children, younger children, and children who have non-authoritative parents are more likely to share their parents' values. This assertion is based on research, discussed below, which indicates that children growing up with authoritative parenting, older adolescents and male children in particular, have been shown to exhibit the most widely differing beliefs from their parents (Dalhouse & Frideres, 1996; Paulson & Sputa, 1996; Harbach & Jones, 1995).

Newman & Muzzonigro's (1993) findings suggest that adolescents from traditional families experience a period of turmoil while forming their own values. This does not necessarily indicate that they will develop different life-long values from their parents, but that they must explore the issues for themselves. Adolescents' ability to feel secure in exploring values that differ from those of their parents is connected to the parenting style practiced by their parents. Widely used parenting style categories include authoritative, authoritarian, permissive-indulgent, and permissive-negligent. Children of authoritative parents tend to have conflicting values with their parents (Dalhouse & Frideres, 1996). This makes intuitive sense because these youths are confident enough in their relationship with their parents to openly disagree about values.

Older adolescents are also more likely to have different values from their parents. As children mature they experience less cohesion with their parents and are more likely to develop their own views (Paulson & Sputa, 1996; Dalhouse & Frideres, 1996). When children move from elementary schools to secondary schools they are introduced to new and divergent values. Additionally, through contacts made in extracurricular activities and increasing work opportunities, adolescents are exposed to a wider range of belief systems. As adolescents age, their peer network expands and their need for parental approval diminishes.

Gender is yet another factor that influences adolescents' values. Speicher (1994) found that during adolescence, girls were more affected by parental moral reasoning than boys. Perhaps this is because parents are traditionally more overprotective of their young daughters; consequently, female children are not as likely to be exposed to situations that give them access to differing beliefs. In addition, they are socialized to be accepting and submissive in our society, which would result in their values being more similar to those of their parents.

It can also be inferred from Speicher's (1994) research that there are, in fact, sex differences. In addition, support for this premise exists in the research of Beutel and Marini (1995) who found that females are both more compassionate and more concerned with the meaning of life than their male counterparts. Again, social norms dictate that females take on these nurturing roles. This difference in socialization would necessarily result in differences in values and belief systems.

The purpose of this study was to determine the effectiveness of value transmission from parent to child. Based on existing research and theories of value formation, we formed several hypotheses. First, we predicted that parents' and adolescents' values would differ. Second, we hypothesized that adolescent females' moral reasoning would be closer to that of their parents' value systems than would their male counterparts. Finally, we proposed that adolescent males and females would differ significantly from one another on values.

METHOD

Participants. Participants for the study were obtained via two E-mail messages. The first of these was sent to the faculty and staff of a small, private college. The second was sent to the employees of a local business. The messages requested voluntary participation be any family with one or two children between the ages of 11-18.

From the advertisements we received approximately 70 responses. Eighteen replies came directly form college faculty and staff in the form of returned E-mails or phone calls and 7 more came in the same form from the employees of the business. In addition, one of the contacts made a at the college suggested seeking more participants from a local church youth group. This resulted in the remaining 45 respondents. Of those who responded, a total of 27 family dyads were actively involved in the study. Three of the families had two adolescents which made the total number of participating families 30 (parents were counted twice as if in two different families for this study).

Over half of the participants were affiliated with the local church and its youth group. The oldest adolescent was 18 and a student at another local college. The youngest participant was 12. The study had 16 male adolescents and 15 female adolescents. Neither race of participants nor age of parents were determined.

Design and Materials. Participants were asked to complete a survey based on Crisman's Moral Behavior Scale (1942). We chose this scale because rating scales have been shown to have a higher predictive validity than ranking methods (Kamakura & Mazzon, 1991). The scale was modified and updated to contain 25 questions relevant to today's society. A Likert scale was used to rate the 'rightness'--1, or 'wrongness'--5 of a given situation. The survey was scored by totaling the numbers associated with the Likert scale for each question. Possible scores ranged from 25 to 125, with a higher score indicating a greater level of conservatism.

Using these values, we attempted to find a correlation between parent values and adolescent values, parent values and female adolescent values, and male and female adolescents values. Predictor variables included gender of adolescent and parental value score. The criterion variable was the adolescent's value score.

Procedure. Packets containing a consent form, an instruction sheet, one parent survey, and one survey for each adolescent in the family were personally delivered to each faculty and a staff member at the college and to each employee a the local business. Fifty survey packets were also given to the director of the youth group at the local church so that he was able to distribute them at their weekly session. All packets were collected within a week of their distribution. A total of 30 surveys were returned.

The parents were instructed to read through the survey and approve it before allowing their child to participate. Once the parent had completed this task, both the parent and the child were asked to sign the consent form. Only the parent who had exhibited interest in the study was to complete the survey. Both the parent and the adolescent(s) were asked to complete the survey individually while at home. Only after both surveys were completed and returned to the envelope was discussion supposed to take place.

RESULTS

Pearson's *r* was used to correlate parent and child value scores. These scores were obtained by summing the numerical responses to each survey question. As predicted, there was no evidence of a significant correlation between these two variables (*r* = .185, N = 30, *p* ≤ .163).

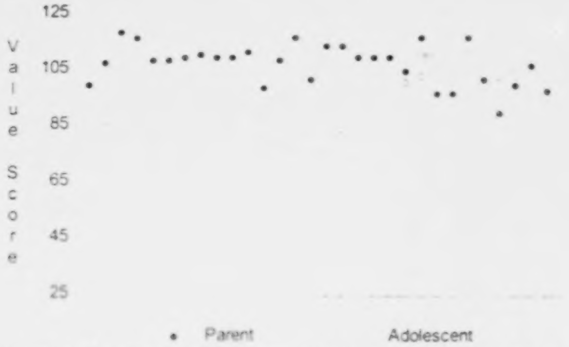

Figure 1. Parents' and adolescents' value scores are shown; each pair represents a parent-child dyad.

Pearson's *r* was also used to correlate the female adolescents' values to their parents' values. It was found that female adolescents tend to have values similar to those of their parents (*r* = .627, N = 14, *p* ≤ .008). There was no significant correlation between male adolescents' values and their parents' values (*r* = -.173, N = 16, *p* ≤ .260).

An Analysis of Variance was utilized to determine a significant difference between adolescent male and female values (*F*(1, 29) = 4.33, *p* ≤ .05). The independent variable was gender, and dependent variable was the adolescents' value scores. The mean value score for the male adolescents was 98.25, while the mean score for females was 105.93. This test indicates that males and females do have different values, and that females are more conservative than males.

DISCUSSION

Based on the results, the study indicated that parent and adolescent values are different. This indicates that the process of value transmission between parents and their adolescents is complex. One possible explanation for this difference in values is that the adolescents may be in the period of turmoil described by Newman & Muzzonigro (1993), during which the adolescent may be exploring many different values and belief systems. This does not necessarily indicate that these individuals will always have values different from those of their parents, but that they are trying out different beliefs to find the best fit. Newman & Muzzonigro's (1993) explanation of the lack of correlations between parents and adolescents values is also consistent with Marcia's (1966) theory of identity statuses and Erikson's (Erikson, 1968) theory of an identity crisis, since both of these theorists also describe a period of turmoil and exploration.

Another explanation for this finding is that adolescents are exposed to many potential sources for values, only one of which is their parents. Today's adolescents, unlike those of past centuries, come into contact with more than just family members. Unlike rural children of past centuries who grew into their parents' occupations as well as their values, modern adolescents are exposed to alternate value systems through their exposure to differing cultural, ethnic, and religious traditions at school, in the community, and even at home in blended families.

After examining the relationship between parents and children, the study also examined gender differences among the adolescents themselves. The research suggests that female adolescents' moral reasoning was more similar to their parents than the values of their male counterparts. This is consistent with Speicher's (1994) study. This may be due to the fact that society traditionally raises male children to be more individualistic and female children to be more submissive to their parents' wishes. As Mlboya (1995) found, parents often act differently towards their children depending upon each child's gender. These actions result in females being socialized to associate more closely with their parents than males.

Finally, the study showed that male and female adolescents' values differ from one another. This supports Beutel and Marini's (1995) research which suggested that there are differences in moral reasoning between males and females. Our results indicate that male adolescents tend to be more liberal than both their parents female peers. Again, this may be attributed to socialization. Based on research previously discussed, it can be assumed that male and female adolescents are treated differently by both their parents and society as a whole. This would offer a plausible explanation for why male and female adolescents' values are significantly different.

While this study has shown that adolescents' values are typically different from those of their parents, female adolescents' values are more likely to be influenced by those of their parents, and male and female adolescents' values differ significantly, it has also established that value transmission is a complex process. While parents play a crucial role in the development of their children, the influences of culture, technology, and adolescents' peers can not be discounted. There are several considerations which should be noted when interpreting this data. They include self-selection of participants, inability to insure identical conditions for all participants when completing the survey, and inability to insure complete privacy within participating families. Because the participants volunteered to take part in this study, generalizations should be made cautiously. Additionally, many of the participants were affiliated with a local church, which may have resulted in a sample bias that could have altered the outcome. It is also impossible to insure that all participants completed the survey in comparable conditions because the surveys were completed in their homes. Therefore, future studies should take these issues into account when planning further research.

Karen E. Brakke and Jeanne M. Stahl

A recent study (Plous, 1996) reported that four out of five psychologists support animal research if it does not involve excessive pain or death for the subjects. However, the general public does not share the same level of support for animal research as the psychologists (Driscoll, 1992). The purpose of this survey was to determine the attitudes of African American college students who have and have not taken a live animal laboratory course. Fifty college students answered a survey dealing with their attitudes toward animal research. Results indicated that the responses of these students were similar to that of the general population. Students who had had research experience with animals responded more favorably than those who had not. These data are from the first year of a longitudinal study which will retest some of the participants after they have been exposed to a live animal research course.

INTRODUCTION

Research with animals has contributed to the control of many infectious diseases. However, there are several activist groups against using animals for research purposes because they feel it is unethical. The animal welfare movement initially focused on the humane care and use of animals: feeding, health care, housing, and alleviation of pain and discomfort. However, the more recent animal rights' movement, also referred to as the "animal liberation movement," has broadened its focus to the extent that animals are no longer viewed as appropriate resources to be used for any purpose by humans (Compton, Dietrich, Smith, & Johnson, 1995).

Animal research has raised many questions such as whether scientists should be allowed to do research that causes pain and injury to animals if it produces information about human health problems. Plous (1996) reported that eighty percent of psychologists support animal research if it does not involve excessive pain or death. That survey, entitled "Animals & Science: A Survey of Psychologists," was mailed to 5,000 randomly selected members of the American Psychological Association; 3,982 participants responded to the survey. Approximately 31.45% strongly supported the use of animals in psychological research, 46.6 % supported the use of animals, 9.1% opposed animal use, 5.0% strongly opposed animal use, and 5.8% responded "Not sure."

Gallup & Beckstead (1988) surveyed 263 college students who had varied majors. They were administered a questionnaire that contained 14 statements about animal research. Fifty-two percent of the participants were social science majors, 15 percent were business majors, 8 percent were humanities majors and 12 percent were undecided. Seventy-six percent expressed a concern about pain and suffering in animals. Approximately 73% percent of the students agreed that "many important biomedical breakthroughs are a consequence of animal research" (Gallup & Beckstead, 1988, p.475).

Pifer, Shimizu & Pifer (1996), reported that in the United States, 42% of the population are opposed to animal research. Past studies with students conducted in the United States have found that women are more likely to oppose animal research than men (Kellert & Berry, 1987). A recent comparison of attitudes in 15 countries found even greater support for animal rights in countries such as France, Belgium, and Great Britain. Because most radical animal activists are of European ancestry, one of the purposes of our research was to compare those students' attitudes with those of African American undergraduate college students. Because several undergraduate research training programs involve the use of animals, also the investigators wanted to determine whether participation in animal research or an animal behavior course might influence them with regard to a research career.

METHOD

Participants. Subjects included 22 male and 28 female college students at a predominately African American small liberal arts institution located in the southeastern region of the United States.

Procedures. The subjects were given a consent form and a brief demographic sheet and a questionnaire about their attitudes towards using animals in research. The questionnaire consisted of 19 questions about their attitudes about using animals in research. Once they completed the questionnaire the participants were instructed to place the questionnaire in an unmarked sealed envelope which was held in a separate box to insure confidentiality of the response. The entire process took approximately 10 minutes to complete.

RESULTS

In this paper we are focusing on questions concerning the need for animal research, personal support for animal research, the use of animal research in undergraduate courses, and the treatment of animals in studies designed to develop treatments for humans. As indicated in Table 1, responses to the questions addressing support of animal research suggested a positive attitude about the role of such research, especially among students who have had research experience with animals. Most of the students, regardless of their experience, believed animal research is necessary, although not all of these students said that they support such research. When asked if the use of animals is necessary for progress in psychological research, most respondents replied "Yes", but the support was greater among those who had experimented with animals. Approximately 74.1% of the participants who had experimented with animals responded "Yes", while 56.5% of those who had not experimented with animals said "Yes" (Figure 1). When asked about their personal support for such research, 59.3% of the students that had experimented with animals reported that they supported (or strongly supported) animal research, while 34.8% of the subjects who had no animal research experience supported it (Figure 2).

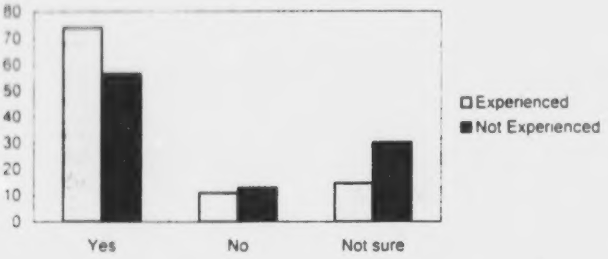

Figure 1. "Do you believe that the use of animals in psychological research is necessary for progress in psychology, or not?"

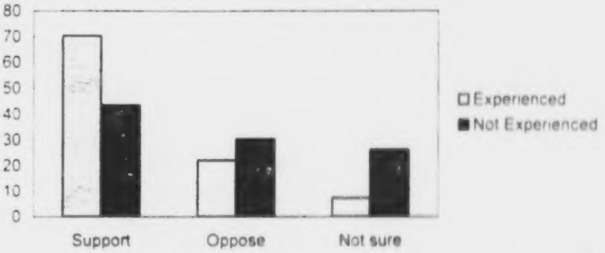

Figure 2. "In general, do you support or oppose the use of animals in psychological research?"

Having animal research experience appears to have a positive influence on some students who are undecided about the necessity of animal research in psychology and their support of such research. Of the subjects who had not experimented with animals, 30.4% answered "Not sure" when asked if animal research was necessary, whereas only 14.8% of the subjects that have experimented with animals said "Not sure". Approximately 7.4 percent of the participants that had experimented with animals said that the were not sure that they support the use of animals in psychological research, whereas 26.1% of the subjects that have not reported that they were "Not sure".

With regard to the use of animals in undergraduate psychology courses, 74.1% of the students who had experimented with animals reported that they supported the use of animals; 47.8 percent of the non-experienced students reported that they were in support of using animals in undergraduate psychology courses (Figure 3). However, support for making animal laboratory courses mandatory was not quite as strong. When asked "Do you feel that laboratory work with animals should be a required part of undergraduate psychology major?", 63.0 % of the subjects that had experimented with animals said "Yes" while only 30.4% of the students who had not experimented with animals replied "Yes" (Figure 4).

877

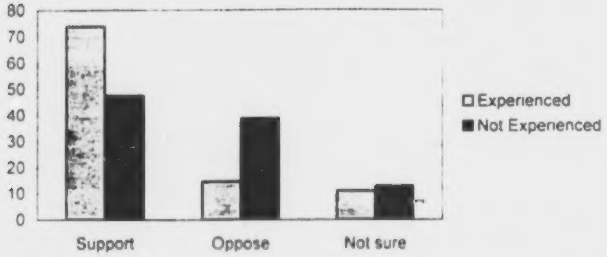

Figure 3. "In general, do you support or oppose the use of animals in undergraduate psychology courses?"

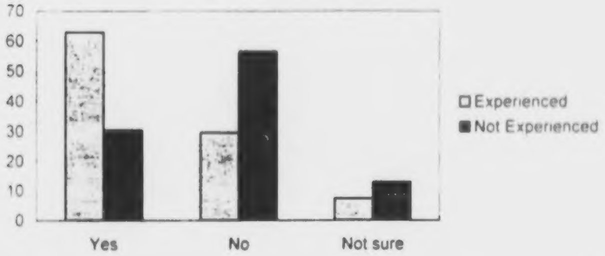

Figure 4. "Do you feel that laboratory work with animals should be a required part of the undergraduate psychology major?"

Experience with animals also appears to make students more sensitive to the well-being of the animal subjects. When asked, "Is it okay to inflict pain on animals to develop cures or treatment for pain or illnesses?," 44.4 percent of the students that had experimented with animals reported "Yes", whereas a majority, or 56.5 percent, of the subjects that had not experimented with animals reported "Yes".

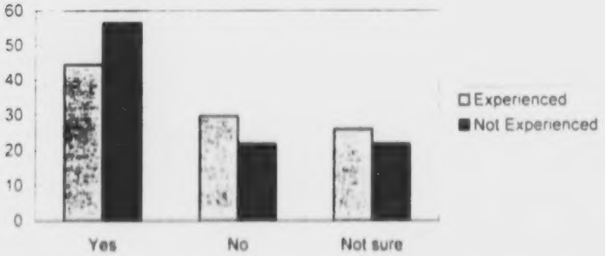

Figure 5. "Do you think it is okay for researchers to inflict pain on animals if it is going to develop cures or treatments for pain or illnesses?"

DISCUSSION

Students who have experimented with animals responded favorably toward using animals in research, while those who have had no animal research experience reported somewhat lower levels of support. One factor that may play a role in the non-experienced students' responses is their lack of familiarity with animal laboratory procedures. Thus, more of these students are "not sure" about their opinions regarding animal research. Having contact with animals in a laboratory situation appears to be a positive experience for many students; opinions tended to shift from "not sure" to support of animal research. It is interesting to note here that many psychology textbooks report data from animal experiments without making it clear that the subjects were animals (Domjan & Purdy, 1995), leaving students to assume that the information came from studies with humans (Cunningham, 1996). This may be an avenue by which to more effectively communicate the contributions of animal research to psychology.

We found that 58% of the African-American students that we surveyed supported animal research. This level is comparable to the level of support reported for college students (64%) reported by Compton, et. al (1995) and for adults in the United States (53%) reported by Pifer et al. (1996). Thus, it appears that these issues are of equal concern to everyone regardless of ethnic background.

Transitive Inference in Undergraduate College Students

Rhea Watson

Department of Psychology
Morris Brown College

Atlanta, GA 30314

Faculty Advisors:
Julianna Lancaster and John Batson

Transitive inference is a process that occurs when one is given specific information and from that information obtains additional ideas and concepts. The study of transitive inference has been performed using a number of animals, including rats and pigeons. Research shows that humans as young as age four are able to quickly infer information. Although most research with humans has used verbal procedures, this study presented information using nonverbal stimuli in undergraduate students. The results suggested that humans do successfully infer information.

INTRODUCTION

Transitive inference is a process that occurs when an individual is given specific information and from that information derives additional facts and concepts. An example is as follows:

1. If Mary is taller than Mike (A>B), and
2. If Mike is taller than Alan (A>C) then
3. Who is taller. Mary or Alan (A vs. C)?

This cognitive process occurs not only in humans, but also in a variety of animals including chimpanzees (Gillan, 1981), squirrel monkeys (McGonigle & Chalmers, 1977), pigeons (von Fersen, Wynne, Delius, & Staddon, 1991) and rats (Davis, 1992).

Transitive inference is more than successful performances on specific tasks, it covers a series of events that must demonstrate proper order and relationship. When these tasks are mastered, a subject's competence in managing transitive inference is made evident. When embarking on the challenge of transitive inference, he/she must rank objects on a ordinal scale and make judgments involving inferential logic. With transitive inference, items that have not been presented before must adopt a value relative to the other items on the scale (von Fersen, Wynne, Delius, & Staddon, 1991).

On tasks involving transitivity, humans are usually able to understand the required ideas if they are presented in a verbal format. All too often, when the information is presented nonverbally humans have difficulties while trying to determine the concept of transitive inference (Batsell, 1993). It is suggested that transitive inference is either the idea that one develops a hierarchy of a linear stimulus developed by Bryant and Trabasso (1971) where a five item series where is labeled as: A+B-B+C-D+E- (+ means correct and - means incorrect) or, transitive inference is the integration of a set of logical operations. Although transitive inference has been demonstrated in a number of species, the processes underlying this performance are not clearly understood (Steirn, Weaver, Zentall, 1995). The present experiment studied the transitive inference abilities of undergraduate students using a nonverbal task. It is felt that this experiment was needed in order to have more complete comparisons with transitive inference between animals and humans.

METHOD

Participants

The participants were 15 undergraduate students from a small liberal arts college located in a large metropolitan city. The students were recruited by advertisements placed around the campus. When applicable, the students received extra credit in psychology classes for participating.

Apparatus

An IBM compatible personal computer was used. Turbo basic was the language used to create the computer program used during the entirety of the experiment.

Training Phase

The participants were asked to sign a consent form and fill out a demographic sheet and to sit at a computer while instructions were read. The instructions explained that each participant should "earn as many points as possible." After the instructions were read and all questions answered the participants saw simple directions on the computer screen asking them to type their initials and press enter. After this was complete the first two semicircles appeared on the screen.

Points were earned by choosing one of two semicircles presented simultaneously. The semicircles appeared on the screen until the participants chose one. The semicircles were one of five colors (red, blue, white, green, or purple). The pairs of colors were represented as: A+B-, B+C , C+D-, and D+E. Each color was randomly assigned to an A, B, C, D and E condition. All the colors were randomized in order to eliminate bias. Also, the stimuli pairs were presented randomly to the participants.

Each semicircle was one and three fourth inches wide and was presented three and one half inches apart. The semicircles were positioned on the middle of a black computer screen that was eleven by eight inches. Each semicircle had a different orientation and position when presented on the screen.

The participants chose the desired semicircle by pressing "F" for the semicircle on the left and "G" for the semicircle on the right. Once this occurred the two semicircles disappeared from the participants view and they saw one of the following screens: If the participants chose correctly, "Correct" appeared on the screen along with a dollar amount total, their accumulated points and a status bar which showed the participants how much time had passed. The reinforcement screen was displayed for two and one half seconds. Furthermore, the participants heard a brief beep each time the answer was correct. If the participants chose incorrectly, "Not correct...try again," a dollar amount total, the participants accumulated points, and a status bar appeared for two and one half seconds. The participants did not hear a beep if the chosen answer was incorrect. The words were presented in a gray color on a black screen. There were five trials given to each testing pair (there were four testing pairs). The Training phase lasted for a total 160 trials.

Testing Phase

During the Testing phase, another set of directions appeared on the computer screen. The directions explained that the participants had done well so far and that they needed to keep up the good work. The participants were told that during this segment of the experiment they would not know the total amount of money earned or how many points accumulated. The participants were reminded to earn as many points as possible although their earnings would remain unseen. In other words, the Testing phase was the same as the Training phase with these exceptions: No feedback was provided on correct/incorrect choices, and all combinations of the five stimuli pairs were tested. The status bar was all that the participants viewed after he/she chose the desired semicircle. The screen was presented for two and one half seconds.

During the Testing phase, the semicircles were presented as the following pairs: AB, AC, AD, AE, BC, BD, BE, CD, CE, and DE . The Testing pair being studied by the experimenter was the BD pair; (this pair was being tested because it had not been presented together previously). The same colors presented to the participants during the Training phase were also used during the Testing phase. All the colors and the stimuli pairs were randomized during the Testing phase.
This part of the experiment lasted through 100 trials. There were 10 blocks with 10 testing pair per block. After the final testing trial, the participants were debriefed, asked if they had any questions, and thanked for their time and effort. A credit sheet was given to the participants for extra credit in their psychology courses. The entire experiment lasted for approximately 20 minutes.

Dependent Variables

There were two dependent variables in this study: the choice made by each participant, using either the "F" key or the "G" key, and the reaction time of each participant during Training and Testing.

RESULTS

The results indicated that the number of correct responses improved over training trials. Initially, mean correct scores were not significantly different from chance (50%). The participants mean score was 69 percent. By the end of Training, the mean correct scores approached 90%. During the final two training trials participants' mean score was 74 percent. The analysis was, that participants learned the correct relations for the four training stimuli.

The most important data are the responses to the BD pair during Testing. B and D were equally reinforced (in BC and DE trials). Because this pair was not trained together previously, participants might not be expected to choose differentially. If, on the other hand, Training promotes a "mental ordering" of the five stimuli, then B should be preferred to D. In the absence of feedback about their choices during Testing, participants did choose the B stimulus significantly more often than predicted by chance. The mean correct response was .67 percent.(standard error equaled .06, 95% confidence interval = +/-13). Participants showed evidence of transitive inference.

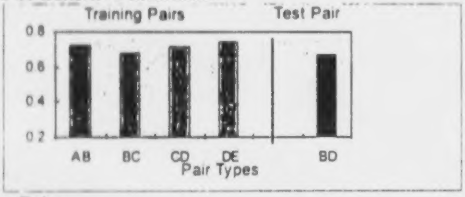

Figure 1 Training Pairs

DISCUSSION

The preference shown for the B stimulus in the BD test trials, demonstrated a logical ordering of the five stimuli. Some researchers argue that this "mental ordering" is established solely because of the reinforcement history. This is especially thought of in regards to the nonverbal approach of transitive inference. Still, others state that there is a more cognitive approach to transitive inference.

One goal of this study was to develop procedures with minimal spoken communication while studying transitive inference in undergraduate students. Because these procedures more closely approximate those used to study similar processes in animals, it is hoped that more thorough comparisons of inferential reasoning among species might now be possible. Proposed future studies will focus on the importance of distance between stimuli, and the effects of punishment during training in transitive inference.

Conflicts of Interest in the Early Stages of Intimate Relationships

INTRODUCTION

Controversial issues in intimate relationships include annoying behaviors, arguments over relationship rules, and incompatible interests (Braiker & Kelley, 1979; Peterson, 1983; Witteman, 1992). Couples argue over how to spend money, how to have sex, how to distribute chores, and how to argue (Christensen & Heavey, 1990). Controversial issues usually differ in how important they are to each partner and how disruptive they are to the relationship. In addition, most partners tend to have some issues where they are willing to compromise, whereas other issues are not negotiable (Rubin, Pruitt & Kim, 1994). The latter ones are often issues where one's own position seems to be more justified and legitimate than the position of one's partner.

Whereas conflicts of interest merely indicate that partners hold different positions on an issue, judgments of legitimacy cast each position as "right" or "wrong" and imply that the legitimate position represents what "ought" to be done, while the illegitimate position "ought to change." Thus, a strong "self-legitimacy bias" may turn a conflict of interest into a battle for influence.

The present paper explores the issues couples are grappling with in more detail. First, which issues were raised by couples? Second, how important and disruptive were these issues for each partner? Third, how did partners perceive the legitimacy of their own position ("self-legitimacy") and the legitimacy of the other's position ("other-legitimacy")? How common were self-legitimacy biases and did they vary by gender or by conflict issue?

METHOD

Sample

Ninety-eight heterosexual couples at two state universities in the northeastern United States completed a questionnaire on conflict in close relationships. The sample was young in age and experience. Among the women, 48 were under the age of 21, 43 were between the ages of 21-25, and 7 were older than 25. Similar results were found among the men with 36 under the age of 21, 53 between the ages of 21-25, and 7 older than 25. Only one couple had been together for more than five years. For 21 women, this was their first relationship and 49 women had only had one or two prior relationships. Prior experiences for the men varied slightly, as only 13 were currently in their first relationship, and 42 had had only one or two prior relationships.

Procedure

The couple arrived at the research facility together; however, they completed all but one section of the questionnaire separately, under complete confidentiality. The participants were not interviewed, nor did they discuss the questionnaire with their partner. The questionnaire consisted of five sections, only one of which was completed jointly. In this, the first section of the questionnaire, each couple described a conflict they had experienced and indicated in a few words on the bottom of the first page what the conflict was about. After deciding on a conflict issue, the partners completed the remaining sections of the questionnaire separately.

Measurements

For this research, ratings on importance, disruptiveness, and legitimacy were analyzed. Each partner rated the importance of their conflict issue on a 5-point scale ranging from (1) very unimportant to (5) very important. A similar scale was used to rate disruptiveness ranging from (1) not at all disruptive to (5) extremely disruptive. Partners described their position and the other's position on the conflict issue and indicated whether they considered each position appropriate, legitimate, reasonable, and justified using four 5-point scales ranging from (1) strongly disagree to (5) strongly agree. Because scores on these four scales were highly correlated, they were averaged to form a single index for self-legitimacy and one for other-legitimacy.

The following example of Bob and Lisa (not their real names) illustrates how a conflict of interest can be intertwined with perceptions of "right" and "wrong". Bob and Lisa had a conflict of interest with regard to Bob's spending habits. Lisa's position was that Bob should take responsibility for his actions and be more careful with money. In contrast, Bob emphasized that he wanted to have fun and believed in living for today, not in worrying about tomorrow. Each partner found her or his own perspective extremely legitimate and discounted the legitimacy of the other's position.

This example shows how partners can evaluate their differences in terms of "I am right, and you are wrong" and thus implicitly place the burden of change on the other.

Content Coding

A coding system was developed to categorize the conflict issue raised by each couple (Sillars, Weisberg, Burggraf and Wilson , 1987; Weber, 1990). During the initial coding, conflict issues were categorized into broad content areas on the basis of the introductory statements listed by both partners. Examples included sex frequency, time together, money, relationship with friends, career choice, living arrangements, and relationships with ex-partners.

For the second coding, additional information from the questionnaire was used. Each partner's individual description of the controversial issue was analyzed to learn more about the conflict. These descriptions included her statements of her own position and her statement of his position as well as his statement of his own position and his statement of her position. The 98 issues were narrowed down to 13 categories. Next, the first and second coding were compared to obtain a final list of content issues. If a discrepancy existed between the first and second coding, the responses were once again reviewed and a category was decided on.

The categories were compared with those of another coder. The 13 categories were collapsed into a final category list of eight topics. A third, independent coder and myself coded all conflict issues again using the final list of eight categories. Our overall interrater agreement was Kappa=.778. Overall interrater agreement and agreement for individual categories was satisfactory.

RESULTS

Conflict Issues

Which issues were raised? Conflicts over relationship rules and third parties were most common. The relationship rules category includes arguments over reliability, dependability, being on time, and neatness, as well as arguments over how to use substances such as nicotine and alcohol, and how to have sex. These issues were raised by fifteen couples; the interrater agreement in this category was Kappa=.873. Third-party conflicts revolve around not getting along with each other's friends or family members and peers interfering with partners' attempts at being a "couple" (n=15; Kappa=.660). Also frequent were conflicts over the couple's future (e.g., to continue or end the relationship, to pursue similar or different careers; n=14, Kappa=.829) and over how much time to spend together as a couple (n=13, Kappa=.829). Twelve couples raised the issue of how to spend money (Kappa=1.000). Eleven couples were arguing over ex-boyfriends, ex-girlfriends, or potential sexual competitors (Kappa=.796). Issues concerning different values were raised by ten couples and included religious differences and different opinions about social issues (Kappa=.748). Finally, eight couples argued about assuming relationship responsibilities (e.g., distributing chores, whether to have children, how to show mutual respect; Kappa=.706).

Importance and Disruptiveness

The second question addressed gender and issue differences in importance and disruptiveness. The mean importance ratings were analyzed using an analysis of variance with issue as the between subjects factor and sex as the within subjects factor. Only the interaction between issue and sex was significant, that is men and women differed in the importance rating for certain issues only. In general, mean importance scores for women ranged from 4.7 for third parties to 3.6 for time; similarly, mean importance scores for men ranged from 4.3 for values to 3.1 for relationship rules.

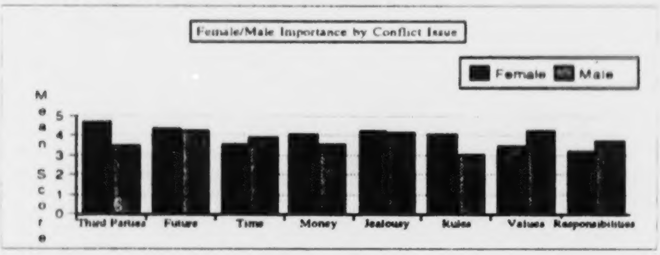

Figure 1: Female/Male Importance Rating by Conflict Issue

However, of the 15 couples who had raised a third party issue, the women's mean score on importance was 4.7, the men's mean score was 3.5. This difference was significant (t(14)=3.83, p=.002). The mean score for women's perceived importance of relationship rules was 4.0, the men's rating was 3.1. This difference was also significant (t(14)=4.18, p=.001). Results for importance ratings are shown in Figure 1.

Did women or men rate the level of disruptiveness of their conflict issue differently? Results of a multivariate analysis of variance with gender as a within subjects factor and conflict issue as a between subjects factor indicated that some issues were more disruptive than others, F(7, 89)=3.47, p=.002; neither the main effect of gender was significant, F(1, 89)=.79, p=.375, nor the interaction of issue and gender, F(7, 89)=1.17, p=.330. In general, both women and men rated jealousy as most disruptive (x=4.1 for women, x=3.9 for men), whereas values received a low disruptiveness rating by both the males (x=2.6) and females (x=2.5). The results of the disruptiveness ratings are shown in Figure 2.

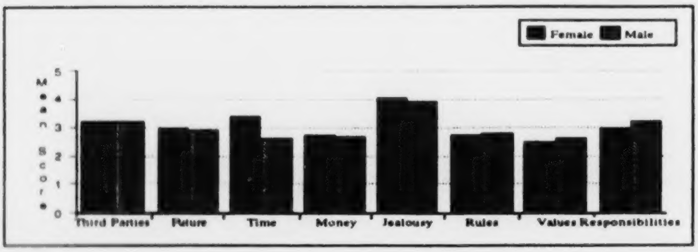

Figure 2: Female/Male Disruptiveness Rating by Conflict Issue

Self- and Other-Legitimacy

Next was the issue of legitimacy. The results of the legitimacy analyses are illustrated in Figure 3. Men and women's self-legitimacy ratings did not differ significantly and were combined in one score. Similarly, men and women's other-legitimacy ratings were not significantly different and therefore averaged.

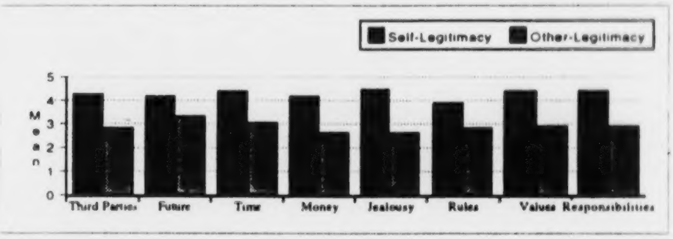

Figure 3: Legitimacy of Position

As illustrated in Figure 3, self-legitimacy was rated higher for all conflict issues while other-legitimacy was rated lower, F(1, 73)=134.06, p=.000. A few of the conflict issues were seen as slightly more legitimate than others, but for the most part the difference was very small, F(7, 73)=1.65, p=.136. For example, self-legitimacy ratings for all conflict issues except for relationship rules were in the range of 4.2-4.5. The rating for relationship rules was 4.0. The same was true for other-legitimacy, conflict issue did not make a difference in legitimacy ratings. All conflict issues ranged from 2.6-3.3. No other-legitimacy ratings were higher than 3.3.

Are self-legitimacy biases larger for some issues than for others? Figure 3 shows that women and men alike display a considerable amount of "self-legitimacy bias." However, closer inspection of the differences between self- and other-legitimacy suggested that women were particularly concerned about self-legitimacy when the conflict was over relationship rules; women's difference score (self-legitimacy minus other-legitimacy) was 2.00, men's was .64, t(13)=1.86, p=.086 (Figure 4). In contrast, men were particularly concerned about self-legitimacy when the conflict was over money ; women's difference score was .80, men's was 1.90, t(9)=2.54, p=.032 (Figure 5).

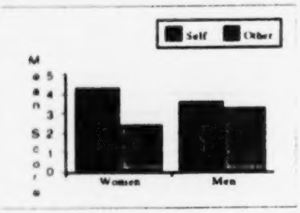

Figure 4:
Self- and Other-Legitimacy for Rules Issues

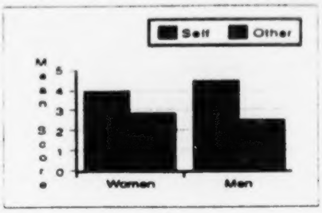

Figure 5:
Self- and Other Legitimacy for Money Issues

CONCLUSION

Controversial issues in this study fell into one of eight categories: relationship rules, third parties, the couple's future, spending time, money, jealousy, value differences, and relationship responsibilities. Problems involving friends or family members (third parties) as well as arguments over relationship rules were more important for women than for men. Both women and men described conflicts concerning jealousy as most disruptive and conflicts over value differences as least disruptive. Across issues, both partners thought of their own interests as the legitimate position while discounting the legitimacy of the other's point of view. Women were particularly clear about the legitimacy of their own position in conflict over relationship rules (e.g., sloppiness), whereas men emphasized the legitimacy of their own position in arguments over money.

This study can give only limited insight into the nature of conflict issues and the impact of issue identification on the conflict process. For example, the couples described only one controversial issue; it would be interesting to examine how the same couple responds to different issues. Also, this study used retrospective self-reports only; a promising research alternative would be to collect data on issue identification in the form of an ongoing conflict diary.

Nevertheless, the present findings highlight features of controversial issues that are central in issue identification. Particularly clear was the tendency to emphasize the legitimacy of one's own interest while discounting the legitimacy of the interests of the other side. This tendency can get in the way of problem-solving because it encourages partners to disregard the other's position, reduces their willingness to listen to the other side, and thus makes it more difficult to work on a problem together (Klein & Lamm, 1996). Partners may be less willing to compromise on conflicts of interest where they are particularly "biased" towards the merits of their own position as compared to issues where they can appreciate the legitimacy of the other's point of view. A "self-legitimacy bias" can fuel a partner's perception that the other is the "source" of the problem. While the merits of one's own position were obvious to most partners in the present study, only in one couple were partners able to appreciate the other's point of view. Although unable to reach consensus, this couple showed mutual respect and avoided the battle for influence.

ACKNOWLEDGEMENT

The author wishes to express her appreciation to Dr. Renate Klein, University of Maine, for her continued encouragement, support and guidance.

Parent report of social adjustment was examined for children and adolescents with juvenile rheumatoid arthritis (JRA) and non-chronically ill comparison peers. The parents of 35 children and adolescents with JRA and the parents of 35 non-chronically ill comparison peers completed the Child Behavior Checklist (CBCL). The Total Social Competence Scores on the CBCL were examined. It was expected that the children and adolescents with JRA would have lower Total Social Competence Scores than the non-chronically ill comparison children and adolescents. It was also expected that the adolescents with JRA would have lower Total Social Competence Scores than the children with JRA. Contrary to these hypotheses, neither illness status (JRA or control) nor age significantly affected the Total Social Competence Scores. The implications of these findings are positive in terms of psychosocial adjustment for children and adolescents diagnosed with JRA.

BACKGROUND

Juvenile rheumatoid arthritis (JRA) is a chronic illness that affects about 250,000 children in the United States today (Schaller, 1980). It is a disorder involving the inflammation and overgrowth of the synovium, the thin membrane lining the space around joints which secretes a fluid that allows the cartilage to move without friction and facilitates joint movement. JRA ranges in severity from pauciarticular (affecting four or fewer joints) to polyarticular (affecting five or more joints) and systemic (affecting internal organs as well as joints) (Cassidy & Petty, 1995). Children with this disease experience periods of stiffness, swelling, and pain in their joints. In addition to pain, fatigue is a common symptom of JRA, and growth retardation and abnormalities are frequent complications of the disease (Cassidy & Petty, 1995). JRA is treated with a strict routine of exercise, medication, nutritional support, and surgery. Although many children and adolescents with JRA outgrow their disease, about five percent of children with JRA have recurrent arthritis as adults, and about 10 percent enter adulthood with severe disabilities (Cassidy & Petty, 1995).

In addition to the above physical challenges, children and adolescents affected by JRA may be faced with social stressors related to the disease, including social development (McAnarney, Pless, Satter, & Friedman, 1974). For example, daily pain and debilitation may make it difficult for children and adolescents with JRA to lead "normal" social lives. Aside from social activities being restricted by physical limitations, children with JRA may be limited further by strict treatment regimens and frequent hospitalizations resulting in an increase in absenteeism from school. It is developmentally important for children and adolescents to feel accepted by their parents and siblings and to find social acceptance beyond their home life.

Several studies have focused on the social impact of JRA, and findings have been equivocal. Some studies have found that children and adolescents with JRA score lower on measures of social competency than either comparison groups (Timko, Stovel, Moos, & Miller, 1992; Zeltzer, Kellerman, Ellenberg, Dash, & Rigler,

1980) or population norms (Ennett et al., 1991). Zeltzer et al. (1980) utilized child report and found that adolescents with JRA experience more illness and treatment-related disruption of body image than non-chronically ill adolescents and other chronically ill adolescents. This study also found that adolescents with JRA experience more problems with parents than non-chronically ill adolescents. Examining a combination of parent and child reports, Timko et al. (1992) found that children and adolescents with JRA participate in fewer extracurricular school activities and fewer activities with friends than non-chronically ill children and adolescents. In relation to population norms, Ennett et al. (1991) concluded that children with JRA have significantly poorer social competence and emotional functioning.

In contrast to the above results, other researchers have found that children and adolescents with JRA do not differ significantly from either comparison groups (Harris, Newcomb, & Gewanter, 1991) or population norms (Thompson, Varni, & Hanson, 1987; Wallander, Varni, Babini, Banis, Wilcox, 1988). Harris et al. concluded from a combination of child, parent, and school reports that having JRA was not associated with detrimental outcomes. Through classroom observations, they found that children with JRA have peer relations that were quite similar to those of children without chronic illness. Through parent report, Thompson et al. (1987) found no significant differences between children with JRA and population norms in social competence scores.

Ungerer, Horgan, Chaitow, & Champion (1988) examined social variables, such as self-perception and social contacts, and their effect on adjustment in children and adolescents with JRA. They found that these variables differed between the age groups. Social adjustment in children was found to be more strongly associated with positive perceptions of the self and others, whereas social adjustment in adolescents was found to be more strongly associated with positive self-perceptions and social contacts outside of the family context. This suggests that social adjustment may be different for children than adolescents. Adolescents have an increased understanding of bodily processes and underlying pathology (Dolgin et al., 1989), but they have yet to acquire adult coping mechanisms (Goldberg & Tull, 1983). Important developmental tasks during adolescence include achieving independence and autonomy from one's parents, establishing a comfortable body image, forming goals for future career development, and finding social acceptance beyond the home environment (Gavaghan & Roach, 1987; Goldberg et al., 1983; Zeltzer et al., 1980). Hospitalizations and being bound to the home due to stiffness and pain generally detract from the amount of freedom adolescents with JRA are able to enjoy away from their home.

A few studies have examined this issue of age and social adjustment in children and adolescents with JRA. In one study, it was found that diminished social competence was weakly associated with older age (Daltroy et al., 1992). However, in another study, it was concluded that age did not significantly affect social competence (Wallander et al., 1988).

Inconsistencies in the current literature may be due to multiple methodological limitations. First, some of the current studies utilize nonstandardized measures (Ennett et al., 1991; Ungerer et al., 1988; Zeltzer et al., 1980). Using such instrumentation results in questionable validity of the results of the study. Second, nonrepresentative samples due to ascertainment bias can produce in skewed results. Finally, some of these studies either do not have a well-matched comparison group (Zeltzer et al., 1980) or have no comparison group at all (Daltroy et al., 1992; Ennett et al., 1991; Thompson et al., 1987; Wallander et al.,1988). A well-matched comparison group is essential in determining whether or not children and adolescents with JRA have poorer social competence than their non-chronically ill peers. Simply comparing the social competence scores of children and adolescents with JRA to test norms may not provide valid results due to cohort effects or regional variations in scores.

It is especially important to utilize a well-matched control group in research involving standardized measures such as the CBCL. Achenbach & Howell (1993) conducted a 13-year comparison study utilizing the CBCL to determine whether the original norms are representative of current populations. It was found that more untreated children in the 1989 sample (18%) than in the 1976 sample (10%) would be considered to need clinical assistance and social competence scores were lower in the 1989 sample than in previous samples. This finding suggests that there has been an overall shift in parent perceived behavior problems, and social competence for children. This evidence of a cohort effect is clear support for the necessity of a well-matched control group when using a measure such as this in research. A similar study was conducted by Sandberg, Meyer-Bahlburg, & Yager (1991). These researchers also found that, of the nonclinical sample of boys, for example, tested in 1987-88, 17% (versus 10% in the CBCL nonclinical sample) fell within the clinical range on the Total Social Competency, and 20% (versus 9%) exceeded the clinical cut-off for Total Behavior Problems. Sandberg et al. also found significant race/ethnicity effects, which also account for regional effects. In the current study a well-matched control group is utilized, a standardized measure of social competence which has been shown to be valid and reliable is used, and ascertainment bias is minimal.

The current study utilizes parental report of social competence on the CBCL to assess social adjustment of children with JRA in comparison to a matched control group of non-chronically ill peers. The Total Social Competence Scores are based on the compilation of the Activities, Social, and School scores on the CBCL. It is expected that the Total Social Competence Scores from the CBCL will be lower for children and adolescents with JRA than for non-chronically ill comparison children. It is also expected that adolescents with JRA will have lower Total Social Competence Scores than children with JRA.

METHOD

participants

Participants were selected from the files of children with JRA who were receiving treatment at the Children's Hospital Medical Center (CHMC). Nearly every child with JRA living within a 50-mile radius of the medical center receives treatment at CHMC because it is the only treatment center in the area staffed with board-certified pediatric rheumatologists. Potential participants were included if they met the following criteria: 1) diagnosed with JRA according to American College of Rheumatology classification standards (Cassidy & Petty, 1995); 2) receiving no full-time special education; 3) between 8 and 14 years of age; and 4) living within 20 miles of CHMC. These criteria generated a potential sample of 40 children with JRA. Four of the families of children with JRA declined to participate, and one family of a child with JRA could not be located.

The comparison participants were selected from the classrooms of the children with JRA. They will be referred to as the matched classroom comparison peers (MCCP). A list of all the children in the classroom of a child with JRA who were the same race and gender as the target child was compiled. The child on the list with the closest birthdate to the target child was then selected. The families of the potential MCCP were contacted, informed about the general nature of the study, and asked to participate. If a family did not agree to participate, the family of the child with the next closest birth date to the target child was then selected, and so on until a family agreed to participate. Only three of the MCCP were not first choices.

This study is part of a larger ongoing project which includes longitudinal data collected from parents, teachers, peers, and children with a variety of chronic illnesses.

measure

Child Behavior Checklist (Achenbach, 1991) The CBCL is a parent report of a child's current social competence. It is composed of 20 social competence items. The focus of the current study is on the 20 items measuring a child's activities, peer relations, and school performance, which compose the Total Social Competence Score. This checklist has been standardized on 1,300 community nonclinic-referred and 2,300 mental health clinic-referred children between the ages 4 and 16, and it has been used extensively in clinical research. Scores on all scales were computed as normalized T scores. Daltroy et al. (1992) found a test-retest reliability of .82 to .90 for this measure, depending on the age/gender of the subgroup tested and found established validity.

procedure

The families of the children with JRA and the MCCP were contacted by phone and informed of the general nature of the study. The parents were told that the data collection would be scheduled at the family's convenience and that they would receive $50 for their participation. The research staff members who collected data were blind to the family's status (JRA or MCCP). Before the actual data collection, each family read a letter explaining the study and the parents and child signed an informed consent. Each parent was given a battery of questionnaires including the CBCL to be completed.

RESULTS

To test the hypotheses, a 2 (Total Social Competence Scores for children with JRA versus those of MCCP) x 2 (age less than or equal to 11.8 years versus greater than 11.8 years) analysis of variance (ANOVA) was used. This test revealed non-significant results (see Table 1), suggesting that social competence for children with JRA does not significantly differ from the social competence of MCCP regardless of age. Follow-up t-tests were also performed for the type of participant (JRA versus MCCP). These results were also statistically non-significant.

Table 1: Total Social Competence Scores of Younger and Older Children with JRA and Comparison Peers

	Younger (n=35)		Older (n=35)	
	Mean	SD	Mean	SD
JRA (n=35)	46.41	12.20	48.71	10.28
MCCP (n=35)	48.47	9.75	47.33	8.60

DISCUSSION

This study compared the social competence of children with JRA to MCCP based on parent report on the CBCL. Two hypotheses were considered in this study. First, it was expected that children with JRA would have lower Total Social Competence Scores than the MCCP. Analysis of the CBCL data revealed that there were no significant differences between the social adjustment of the children with JRA and the MCCPs. Secondly, it was hypothesized that older children with JRA would have lower Total Social Competence Scores than younger children with JRA. Analysis of the CBCL data also revealed no significant difference in social functioning between older and younger children with JRA. The implications of the results are positive ones for children diagnosed with JRA. The results suggest that the social adjustment of children with JRA and healthy comparison peers does not differ significantly. This outcome suggests that parents believe children with JRA have adequate coping strategies in dealing with their chronic illness and that they are socially accepted and well-adjusted.

Several factors may have led to insignificant results in this study. First, due to the relatively small sample size, power was limited. A larger sample may detect more significant differences. It is also possible that parent report may not be the most accurate report of a child's social adjustment. Perhaps self-report of the children or information from teachers or peers would have revealed significant differences in terms of social adjustment. Lastly, parents may have reported higher levels of social adjustment than actually was the case because they did not want their children to seem "abnormal."

Future research in this area should include child, teacher, and peer reports of social adjustment as well as parent report. Analysis of longitudinal data would be useful in determining changes in social adjustment throughout children's lives (e.g., possible change at the beginning of adolescence, change when the disease goes into remission). Also, it would be intriguing to administer a measure determining coping styles to children with JRA as well as to the healthy comparison children to determine if coping style is related to social adjustment.

The Relationship Between Nicotine and Alcohol Dependence: Treatment Implications

Dr. Barbara J. Mason

Department of Psychiatry and Behavioral Sciences
University of Miami School of Medicine

Several studies have demonstrated an extreme correlation between today's most common addictive behaviors - smoking and alcohol consumption. This link may be biological in nature. Indeed, the endogenous opioid system supports each addiction to some degree, permitting the symptom-substitution hypothesis, in which increased smoking would be considered a replacement for alcohol consumption. Some alcoholism treatment centers even encourage smoking in the belief that this may facilitate alcohol abstinence. In order to investigate the validity of such therapeutic strategies, 19 participants in a 12 week outpatient alcoholism treatment program were evaluated for changes in smoking and drinking patterns. Though data indicated a significant decrease in alcohol consumption and a significant increase in smoking, these changes were not significantly related. Thus, the lack of support for the proposed symptom substitution hypothesis, as well as the strong positive correlation between smoking and drinking levels during pretreatment, advocates a need for introducing smoking cessation approaches to recovering alcoholics.

BACKGROUND

Research has established smoking and alcohol consumption as the two most prevalent addictive behaviors in the world today. Several studies have also indicates an unusually high positive correlation between both behaviors (Bobo 1983, Walton 1972, Bobo 1993, Burling 1988). Indeed, rates of smoking are two to three times greater amongst alcoholics than amongst the general population (Burring 1988, Kozlowski 1986), and smokers are ten times as likely as non-smokers to be alcoholic (DiFranza 1990). The profound implications of these associations on health and treatment methodology have galvanized research on substance abuse disorders and addictive behaviors - the dynamic interplay of alcohol consumption and smoking is now a fundamental motif in scientific inquiry.

Both addictions are partially maintained by the endogenous opioid system. This relation permits the symptom-substitution hypothesis, in which smoking may be viewed as a substitute in an endogenous opioid system withdrawing from alcohol. Thus, many alcohol treatment centers maintain that smoking cessation attempts antagonize alcohol addiction therapies and increase risk of relapse (Bobo 1983, Miller 1983, Hurt 1994). Therapists may even encourage smoking in the belief that this may facilitate alcohol abstinence.

METHOD

In order to investigate the validity of such therapeutic strategies, we investigated smoking and drinking patterns in 19 alcoholics participating in a 12 week outpatient alcoholism treatment study. Patient demographic assessments reflected the sample's mean age, as well as gender and ethnic distribution.

We determined the correlation between smoking and alcohol consumption in alcoholics prior to alcoholism treatment, as well as the relationship between changes in smoking and drinking patterns during the twelve week treatment period. Study assessments included

BEST COPY AVAILABLE

pretreatment measurements of smoking and drinking levels, weekly self-reports of number cigarettes per day, daily drinking diaries, weekly breathalyzers, monthly verification of drinking by friend or relative, monthly Liver Function Tests, and Alcohol Use Histories. Each patient reported to the treatment center once every week for a period of twelve weeks in order to complete designated surveys and tests. Patients also maintained individual logs of smoking and alcohol consumption throughout the twelve week study period.

Data analyses involved student 2-tailed t-tests, correlation tests, as well as mean and standard deviation measurements for demographic characteristics.

RESULTS

Results indicated that pretreatment smoking and drinking levels were highly correlated ($r = .58$, $p < .01$). Data analyses also revealed a significant increase in smoking ($t = 2.46$, 2-tailed significance = .02), and a significant reduction in alcohol consumption ($t = 5.05$, 2-tailed significance = .00) across treatment conditions. These changes, however, were not significantly correlated ($r = .03$, $p = .90$).

Demographic characteristics indicated a mean age of 42.83 years (reflecting an 18 patient sample size) with a standard deviation of 9.5 years. The majority of the 19 patient sample was male (68.4% male; 31.6% female). Caucasians represented the vast majority of the 19 patient sample (84.2% Caucasian, 10.5% Hispanic, 5.3% Unspecified).

CONCLUSION

The strong correlation between smoking and alcohol consumption during pretreatment, as well as the lack of support for a hypothesized substitution of smoking for drinking, emphatically pronounces the need for an effective smoking cessation approach amongst recovering alcoholics. Treatment centers, therefore, should work towards constructing and executing detailed smoking cessation procedures with their alcoholic clients (Bobo 1983). Indeed, treatment programs should focus on controlling or eliminating both dependencies simultaneously; as smoking and drinking levels seem to be highly correlated prior to treatment, such a singular approach to these dependencies may even yield synergistic effects (Miller 1983).

Social Isolation of Nursing Home Residents and Their Perceived Health

Jennifer Langford

Department of Sociology
Wittenberg University
Ward Street at North Wittenberg Avenue
Post Office Box 720
Springfield, OH 45501

Faculty Advisor
Dr. Jerry Pankhurst

The study examined eleven indicators of social isolation and assessed relationships to the perceived health of three care levels in a nursing home. Social isolation was operationalized by the question focused on social interaction. The quantitative measures used to assess the level of social isolation included frequency of visitation with children, family living within fifty miles, family living outside of fifty miles, friends in the home, and friends outside of the home. In addition the number of moves within the home, distance from last residence, and the existence of a person to whom they feel close with inside and outside of the home, were used to assess social isolation. There was no significant relationship found between social isolation and perceived health. However, other significant relationships between frequency of visitation and level of care were discovered. The examination of the variables was hampered by a small sample from one of the care levels.

INTRODUCTION

Social isolation has been extensively researched in the general area of the elderly. Of those studied the largest proportion live at home. In contrast, little research has specifically focused on social isolation of nursing home residents. In literature social isolation is commonly operationalized as little or no personal relations in areas of family, friendship, care-giving, community, and peer groups (Rubinstein et. al. 1994; Chappell and Badger, 1989; Lumpkin, 1990; Townsend 1957).

It is necessary to understand social isolation because the denial of meaningful social contacts has negative effects on individuals. A considerable amount of evidence supports the importance of social networks and social support to health and well-being among the elderly (Rubinstein et. al. 1994, p. 58). Research has shown that the more socially isolated individuals are, the less healthy they are (House et. al. 1988, p. 241). It is apparent that social isolation has detrimental effects on individuals. Due to the expected increase in the utilization of nursing homes from the proportion of elderly growing at a phenomenal rate, it is necessary that social isolation assessments are developed to evaluate the living conditions of residents.

LITERATURE REVIEW

While there no assessment designed specifically for nursing home residents, one researcher has had a profound effect on the way social isolation is measured. Lubben (1988) researched to assess actual and potential social isolation among the elderly. The Lubben Social Network Scale consists of a ranking of family networks, friend networks, confident relationships, and living arrangements, collapsing distinct levels of interaction into two categories; family and friends (Lubben, 1988, p.48).

Other factors must be incorporated into an assessment that evaluates institutionalized elderly. Individuals in an institution have different governing structures over their lives. Of the many influences, one significant influence over the life of an institutionalized individual is relocation within the institution (Wells and Macdonald, 1982, p.181). Another, important influence is the distinction between friends within the home and friends outside of the home. A lack of distinction may lead one incorrectly assess an individual (Biztan and Kruzich, 1990, p.385). Lastly, a crucial factor in determining the amount of social isolation is distance from where the residents moved (Hook et al, 1982, p. 427).

METHODOLOGY

The purpose of this study was to explore the relationship of social isolation and perceived health of nursing home residents. The data for this study came from interviews conducted on a sample of fifty-six residents from a home, in Clark County, Ohio. In order to accurately examine the relationship between the two variables, the residents interviewed were divided into subgroups, according to the level of care received. The three levels of care examined were independent living, assisted living, and nursing home care.

Each randomly selected nursing home resident was asked if they perceive their health to be; 1. excellent for your age (never prevents activities), 2. fair for your age (occasionally prevents some activities), 3. poor for your age (very often prevents some activities), or 4. bad for your age (health troubles or infirmity all the time - prevents most activities or requires confinement to bed). Residents were then asked questions about their social life; 1. frequency of visits with children, 2. frequency of visits with siblings, 3. frequency of visits with other family members, 4. frequency of talking on the phone, 5. frequency of visiting with friends inside the nursing home (meaning the entire campus, residents were informed of this), 6. frequency of visiting with friends outside of the nursing home, 7. frequency of leaving the home (for what activities), and whether these are daily events, weekly events, monthly events, events that occur two to four times a year, yearly, less than yearly, or events that due not occur at all.

In addition to these questions, three questions about the social circle of the residents and persons to whom residents felt close, were asked. One question asked the residents to describe the people in their social circle. A second question asked residents if they have a person to whom he or she feels close in the home and to describe the nature of the relationship. A third question asked residents if they have a person to whom he or she feels close outside of the home and to describe the nature of the relationship. Seven final questions were asked, how long the residents have lived in the facility, how old the residents are, how the residents are feeling on that particular day, how many children the resident has, how the resident describes his or her living situation, how many moves the resident has made in the home, and where the residents lived before placement into Ohio Masonic Home.

To determine if social isolation existed, residents' social interaction was examined using the previous questions. Relying heavily upon the Lubben Social Network Scale, the answers to the questions were coded to evaluate the level of social isolation. This assessment reproduces the numerical assignment. The more frequent the interaction, the larger the numerical value assigned. The largest value assigned is five and the smallest value assigned is zero. There is an exception for the number of moves in the home. The number of moves in the home was subtracted from the total score. The numerical values are totaled to arrive at the score. The total possible score, assuming that there are not moves, is fifty. This social isolation assessment acknowledges and equally accounts for individuals with varying types of social interaction.

RESULTS

A brief look at some of the characteristics of the participants provides a general overview of the home. First, in examining age, there are a large number of individuals in both the 70 to 79 and 80 to 89 age bracket. Overall each of these two categories account for 39% (or 78% total) of the participants. Second, males accounted for 55% of the participants and females accounted for 45%. Third, 11% of the participants came from Springfield, 29% from within 50 miles, 32% outside of fifty miles, and 29% came from out of state. Fourth, 82% of the nursing home residents live by themselves, as compared to 16% of independent living and 60% of the assisted living residents. It should be noted here that individuals live with their spouse or by themselves, not with an unrelated other. Fifth, 96% of the residents from independent living have never moved, compared to 40% for assisted living, and 18% for nursing care. A significant fact is that 55% of the nursing home residents have been moved three or more times.

When examining relationships inside the nursing home, approximately 84% of the residents reported having a person who they felt close to, living inside of the home, whereas 16% of the residents said there was no one who fit this description. There were

BEST COPY AVAILABLE

great variances associated with feelings of closeness and the level of care. Of the nursing home residents less than 65% reported feeling close to someone, and 36% felt close to no one. The levels were quite different for assisted living. Of this group, 95% of the residents said there is a person in the home they feel close to. Similar findings were found for the independent living residents, nearly 90% of these residents; reported having a close friend in the home.

Residents reported various types of individuals as close friends within the home. Overall 68% of the residents reported a resident as the person to whom they feel close. While 7% reported a spouse, 2% reported a nurse, and 7% reported other staff. Particularly interesting is the differences in nursing home and assisted living care. Of the individuals in assisted living 95% reported being close to another resident, as compared to only18% of nursing home residents who reported being close to another resident.

When examining relationships outside the nursing home, over 90% of the residents interviewed reported having a person they feel close to outside of the nursing home. The person that the resident feels close to outside of the home varies greatly by level of care. Of the nursing home residents, 45% reported the person they feel close to as their child. This compares with 12% of independent living and 15% of assisted living. The great majority of the residents reported that the person they are close to, outside of the home, was a friend. Of the independent living residents, 72% reported this, and 75% of the assisted living residents reported the same. However, only 35% of the nursing home residents reported that a person they feel close to outside of the home is a friend.

Visitation by family includes three variables: visitation by children, visitation by family less than fifty miles away, and visitation by family more than fifty miles away. In contrast, visitation by friends includes two variables, friends who live in the home and friends who live outside of the home. Overall, 34% of the visitation by friends occurred daily. The overall visitation by friends on a daily basis has little variation in the various levels of care. Of the independent living residents, 20% reported visitation on a daily basis, as compared to 48% of the assisted living residents, and 41% of the nursing home residents. The only noticeable difference lies in the visitation of nursing home residents. Of the nursing home residents, 27% of the visitation by friends occurs two to four times a year. This is compared with 13% of assisted living residents and 4% of independent living residents.

Overall, the frequency of visitation by family occurred the greatest in the period categorized as less than yearly. Approximately 36% of the visitation of residents by family occurred less than yearly. This is illustrated in independent living with 35% of the residents reporting visitation by family less than annually, 40% in assisted living, and 33% for the nursing home residents. However, nursing home residents received the greatest amount of visitation by family, on the most frequent basis.

As for the perceived health of the residents, approximately 36% of the residents stated they perceive their health to be excellent for their age. This is compared with 63% of the residents who perceived their health to be fair for their age. There are large differences with perceived health and level of care. While 63% of the total sample perceived their health to be fair, 82% of the nursing home residents perceived their health to be fair. However, there are strong similarities between independent living and assisted living. Of the independent living residents, 44% perceived their health to be excellent, compared with 40% of the assisted living residents.

Table 1. Social Isolation and Perceived Health of Residents

Social Isolation	Perceived Health			
	Excellent	Fair	Poor	Total
Isolated	0	3	1	4
Possible Isolation	2	6	0	8
Not Isolation	18	26	0	44
Total	20	35	1	56

As for social isolation, approximately 79% of the residents were not found to be socially isolated or possibly socially isolated. Again there was some variance according to care level, however, very few were found to be isolated. Of the individuals in nursing home care, 18% were found to be socially isolated, and 18% were found to possibly be socially isolated. Of the individuals in assisted living 5% (one individual) was found to be socially isolated, and 20% were found to be possibly isolated. Of the individuals in independent living only one individual was determined to be socially isolated, and two (or 4%) were determined to be socially isolated.

No significant observation was discovered between social isolation and perceived health. The individuals who were socially isolated perceived their health to be fair or poor. Additionally, the possible isolates perceived their health to be in the excellent and fair categories.

THEORIES AND HYPOTHESES

In general there appeared to be no significant correlation between social isolation and perceive health. Overall, individuals reported perceiving their health as quite well. This is somewhat surprising with past research in mind. Studies have shown a correlation between levels of isolation and health. However, there are no studies to compare the levels of social isolation of the residents of the home were this research was conducted . It may be that most of the people in the home are genuinely satisfied.

The low levels of isolation that have been discovered do not seem to be explained by the frequency of visitation by family. Residents, generally speaking, receive infrequent visitation by family. Across all levels of care, the greatest frequency of visitation occurred less than yearly. There was little difference when comparing independent and assisted living. However, nursing home residents reported the greatest amount of visitation by family to occur on a monthly basis. This is not difficult to explain, considering the frequency of visitation by friends. Subsequently, nursing home residents received less visitation.

The higher levels found in the frequency of visitation do explain the low levels of social isolation, as over 50% of the visitation with friends occurred on a daily or weekly basis. It should be restated that the statistics include friends outside the home and inside the home. However, it is not surprising that the group with the highest amount of visitation was assisted living, because these individuals eat lunch and dinner with each other on a daily basis. They have incentives to meet others. Life for these residents is very similar to life in a college dormitory. However, life for independent living and nursing home residents is very different. Independent living residents, do just that, live independently. There is little interaction amongst this group of individuals. Nursing home residents eat in their rooms and many are not allowed to venture freely throughout the complex. For these residents there is less of an incentive, or possibly not even the ability, to venture out and socialize.

Generally, people were very satisfied with the institution and what it has done for them, although this varied somewhat by level of care. In independent living and assisted care comments were only positive. One resident said "they do every thing to make life pleasant." Another stated that "we do as we please, we have anything we want." A common comment was that there were "no restrictions." This satisfaction appears to come from the quality of care, the highly integrated group cohesion, and the great number of activities. Residents reported a highly qualified medical staff. Residents also spoke of a bond that exists within the home. A resident stated that there is "a bond you do not find anywhere else." Another resident said, "other homes don't have the ritual bond ... people here are all brothers and sisters (Masons and Eastern Stars)." Other residents said, "we all have so much more in common than other nursing homes ... we all have something we can talk about." Residents also spoke about the number of activities in the home. One resident said "everyone who comes in is amazed ... at the activities." However, this overall sense was not the same for the nursing unit. A great number of residents spoke about being lonely.

This positive feeling about the home is reflected in the number of residents who reported a resident being the person to whom they felt close within the home. Assisted living and independent living residents spoke of high interaction. Of the assisted living residents, 95% reported another resident as the person they feel close to in the home, this compares to 68% of the independent living residents. Opposed to this, more of the nursing home residents spoke of loneliness. Of the individuals in nursing home care, 36% reported not feeling close to anyone.

Although there was little correlation found between social isolation and perceived health, other significant correlations presented themselves. Interesting findings were ones that compared various levels of care. In the areas studied, the residents from independent and assisted living generally responded similarly, and differed greatly from the residents in nursing home care. Each of the variables analyzed indicated a significant difference. The perceived health, number of moves within the home, and the numbers of residents having a person in the home they were close with, all varied greatly from the individuals in other levels of care. These differences help to explain the differences in social isolation. Residents with higher levels of care (nursing) have a far more regimented and controlled life. Nursing home residents lead a life that is enclosed, supervised, and carefully administered. Although, assisted living residents live in the same institution, they have a greater amount of freedom and control over their life. This control over lives of the nursing home residents greatly influences the way in which they interact and how they perceive themselves.

CONCLUSION

More accurate assessments of social isolation are necessary. Previous research has shown a direct correlation between social isolation and physical, psychological, and emotional problems. However, no solid social isolation assessment has been developed to accurately include and measure the housing situations of the elderly, including institutions. Only through future research can assessments be developed and tested.

It is imperative that accurate means of assessing isolation are established. There is a large bulge in the population, the Baby Boomers are about to confront us as elders, and we do not have the means necessary to evaluate their problems. Only through an accurate identification of the problems can we enstate policies to deal with and prevent unnecessary suffering on the part of the elderly and the rest of society.

The Effects of Minority Influence on Group Polarization

Kelly Murphy

Department of Social Sciences

Jennifer J. Dose and Jeff Ratliff-Crain

Trends in the work force today include an increase in women and minorities and greater use of teams. This study examined gender and the effects numeric minorities have in the decision making process and group polarization. It also examined type of influence used in discussion, specifically normative or informational influence statements. Subjects selected from a midwestern University (N=144) were divided into groups of three, with four separate conditions based on gender composition and presented six scenarios involving risk. Decisions before and after the group discussion were obtained. Analysis revealed that participants polarized on some of the scenarios. Women tended to make more normative statements, whereas men tended towards informational statements. However, when a minority, males did not have a greater amount of influence over the majority than did female minorities, as was hypothesized.

BACKGROUND

Companies across America are experiencing an increase in workforce diversity. With this changing tide comes a difference in the way people may interact in the business world. In addition to the increase in work force diversity, a major trend in the work force is the use of teams to make decisions and complete projects. As a result of company down-sizing and re-engineering, production teams often make decisions that were once reserved for upper-level managers (Bennet, 1994; "I.B.M..", 1994). When individuals form a group, various forces come into play, including polarization and influencability, based on the makeup of the group. This study examined the effects that the interactions between men and women have in the decision making process, specifically in relation to group polarization. Group polarization is the phenomenon that group members will become more extreme in their opinions and advocate a more risky or more conservative position when they make a decision with others than they would if they thought about their position without discussion (Stoner, 1961; Kogan & Wallach, 1964; Kogan & Wallach, 1967). In addition to group polarization, the study also examined the type of influence, specifically informational and normative statements as a function of gender, during the course of the discussion.

Groups are swayed by two types of influential pressures, normative and informational influence. Normative statements involve primarily opinions or personal statements used to influence another person. Deutch and Girard (1955) define normative influence as what results when one conforms, complies, or obeys in order to gain rewards or avoid punishment from another person or the group. Normative influence is used to enhance one's position in the group, to maximize social rewards such as acceptance and status (Pruitt, 1971; Sanders & Baron, 1977). The members may feel that to be seen as a good group member they must adopt to a position that is at least equal to or more extreme than the other members', causing group polarization (Isenberg, 1986).

In contrast, informational influence occurs when one tries to persuade others through novel, valid arguments with the use of logic or verifiable facts (Bishop & Myers, 1974). Group members seek information about reality from other group members when they don't know the degree of risk or correct attitude that they should have on a situation. The desire is to arrive at the correct solution to a problem and to have accurate views (Deutch & Girard, 1955). Thus, under this type of influence others' reasons or facts about an issue are more likely to shift opinions to the extreme, because a majority's opinions are often seen as more correct than individual's, even one's own.

Hypothesis 1: Participants would become more influenced, and thus polarized if they were members of a homogeneous group (that is, all three members of the same gender) than if they were members of a mixed gender group of two males and one female, or two females and one male. This would likely happen because homogeneous groups would be more cohesive (Byrne, 1971), leading to more interpersonal influence and polarization.

Hypotheses 2 and 3: Males will make use of more informational influence statements, and females will make use of more normative influence statements (Tannen, 1990). Eagly (1987) proposes these gender differences in influence are due to social relations styles associated with gender roles. Stereotypically, a woman is more likely to use a communal style, and exhibit a concern for others' welfare and feelings, and interpersonal relations within the group. This involves the use of more normative statements. Conversely, males tend to use agentic orientation in conversation, which focuses on task demands, adequacy and correctedness. This orientation incorporates more use of informational statements. (Bakan, 1966; Eagly, 1987). These differences were also supported in research by Dose (1995) who found that women had a lower proportion of giving informational influence, thus reflecting the more communal and less dominant types of interaction in which women engage.

Hypothesis 4: Due to the power differentials between men and women, the male minority would influence the two females to a greater extent than the female minority would influence the two males. Research by Eagly and Wood (1985) suggest that differences in conformity are the result of different social roles occupied by men and women. If females are more likely to feel that they are in a position of low status, they will be more influenceable than males. Research has also shown that both male and female groups are more prone to influence of a male than a female, even though both are equally competent at the task (Ridgeway & Jacobson, 1977). In addition to these social role differences, others have found that informational influence is a more effective form of influence when both forms are introduced (Burnstein & Sentis, 1981; & Kapan & Miller, 1983). Thus, if women tend to use more normative statements, instead of the more persuasive informational statements, they may not be as effective at influencing others

SUBJECTS

The participants were 144 college students, primarily of traditional college age. Students received extra credit for their participation. They were randomly placed in groups of 3 based on gender, for a total of 48 groups. There were four conditions with 12 groups in each, based on gender and group homogeneity: (1) three males, (2) three females, (3) two females and one male, (4) two males and one female.

MATERIALS

Six scenarios adopted from Kogan and Wallach's Choice Dilemma Questionnaire (1964) were used. Only two scenarios were exactly as stated in their questionnaire. The others were similar to the originals but were adapted to illustrate non-traditional gender role dilemmas. Each of the scenarios required the participant to mark the odds of success they would desire before advising the individual in the scenario to undertake this risky yet, more desirable alternative. For example, a family must decide whether the father should take time off work in order to care for the child, something he wants to do, while the mother resumes her job as an account executive. If he leaves his job, he can't return, and the family worries they will not be able to survive financially on her income alone. The participant would mark the odds on a continuum from 1 in 10 to 10 in 10. If they marked a 1 in 10, there is only a 10% chance that they could survive financially on her income, but if the participant thinks the benefits of him staying home with the child is worth taking the 90% chance that they will not be financially secure, they would mark that line. Conversely, if they would only advise the father to stay home if it is certain they won't run into financial trouble, they would mark the 10 in 10 line, or they could mark any one line in between the two extremes, depending on how they felt about the situation. Participants also answered 15 questions taken from the Attitudes about Women Questionnaire (Spence &

Helmreich, 1978) to measure their thoughts on the roles of women in society. Another questionnaire elicited thoughts on the group decision making process.

PROCEDURE

The experimenter briefly described the task to the participants. Group members were then each given a packet that contained six scenarios from the Choice Dilemma Questionnaire. After they individually advocated the odds on each scenario, these packets were collected and they were given the same packet of scenarios again, this time to discuss with the other two group members. This portion was audio-taped, to allow coding of the decision making and influencing processes at a later time. The participants discussed each scenario and gave reasons for why they marked certain probabilities. They had to reach a unanimous decision on each. After the discussion phase, they were given another scenario packet for a third time, in which they again answered the questions individually.

RESULTS

The following table lists the differences in the mean odds advocated by all individuals from Time 1 (Individual), and Time 2 (Group discussion). Overall, across gender and conditions, polarization occurred in three of the six scenarios. ANOVA's showed a movement toward greater riskiness in scenarios 4 and 6 and greater caution in scenario 5 ($F_4(1,138)=7.91$, $F_5(1,139)=6.69$, $F_6(1,139)=4.45$, all p's<.05, see Table 1).

Table 1:

MEAN LEVEL OF ODDS ADVOCATED BY SCENARIO

	Time 1	Time 2
Scenario 1	6.50	6.81
Scenario 2	5.24	4.96
Scenario 3	5.48	5.56
Scenario 4	5.80 •	5.37 •
Scenario 5	8.03 •	8.47 •
Scenario 6	6.88 •	6.27 •

• significant at p<.05

Effects of group homogeneity on polarization were tested using repeated measures ANOVA's. Homogeneity effects on group polarization as predicted in the first hypothesis were only found for scenario 6 (F(1,138)=14.80, p<.001). Here, homogeneous groups experienced more polarization (mean shift=1.02) and thus advocated a greater shift from their individual responses than did the mixed groups (mean shift=.15).

Gender differences in polarization were found only for scenario four. Males became more risky during Time 2 than did females (F(1,139)=15.54, p<.001). The table below illustrates the differences between male and female risk advocated. Additionally, in this scenario, the three-way interaction between gender by condition by polarization was significant, (F(1,139)=9.37, p<.01).

Table 3: Differences between odds advocated in Time 1 & Time 2 for Scenario 4

	Time 1	Time 2
Males	5.32_{ab}	4.69_{ac}
Females	6.28_{b}	6.01_{c}

(Smaller numbers indicate greater risk, like-subscripts reflect significant differences, p<.05).

The second hypothesis that males would make use of more informational statements was supported in this study. A simple factorial ANOVA compared the total informational statements by gender and by group condition. Males used a significantly greater amount of informational statements (mean = 26.18) than females (21.86) (F(1,139)=4.764, p<.05). Homogeneous groups used more informational statements (mean = 27.85) than the mixed gender groups (mean = 20.19, F(1,139) = 9.859, p<.001). In addition, there was a two-way interaction between gender and homogeneity of the group (F(1,139)=11.682, p<.001). The Tukey-Kramer test was used to examine the comparison of the means among the different conditions. This confirmed that males in homogeneous groups shared more total informational statements than did any of the other groups (p<.01).

Homogeneous male groups made a significantly larger amount of total statements ($M_{homog.}$ = 74.86, M_{mixed} =52.64) than the males in mixed groups F(1,139)=8.718, p<.01). Thus, I felt it necessary to look at the percentage of statements that were informational in nature, as a way to control for total statements made. Again, the interaction between gender and homogeneity was significant (F(1,140)=6.493, p<.05) and the Tukey comparison again confirmed a greater percentage of informational statements by males in homogeneous groups compared to any other group (p<.01). It was found that 44% of the total statements that men in homogeneous groups voiced were informational in nature.

The third hypothesis as stated was not supported in the study. Women did make a significantly larger amount of normative statements (mean =21.97), regardless of homogeneity of the group, compared to the males average of 18.97 statements (F(1,140)=4.19, p<.05). However, in examining the percentage of total statements that were normative in nature, the interaction between gender and homogeneity was significant (F(1,140)=20.646, p<.001). The Tukey comparison test confirmed that the males in homogeneous groups made a significantly lower percentage of normative statements than any of the other groups (p<.01). Thus, it can be seen that although the all female groups and the mixed groups tended to make about the same percentage of normative statements, it was the male homogeneous groups that seemed to avoid these statements, and only used them in 24% of their total statements.

Hypothesis four was not supported in the present study. In examining if the gender of the minority had an effect on the amount of influence over the majority, no significant differences were found. However, they are in the direction as hypothesized in that males were seen as having slightly more influence over the women in the group and women in the minority were seen as having the least amount of influence.

CONCLUSION

It has become necessary to look at how genders influence one another in the working arena. In addition, it is important to examine how various combinations of group composition based on gender may affect the outcomes of these group-made decisions. In the present study, group polarization occurred in the last half of the scenarios, possibly from increased cohesion among the group, which motivated them to polarize to a greater extent. Depending on the scenario, groups became either more risky or more cautious when they discussed the scenarios.

When groups come together to make decisions, group members may differ in the style of influence they employ to persuade others. The present study found that males used more informational statements and, contrary to predictions, females did not use more normative statements. Instead, males in a homogeneous groups used fewer statements of this type. This difference in the type of influence used in conversation may affect how influential one may be to others. These stylistic differences support past research that females will have a more difficult time influencing the majority, yet there was only a slight, non-significant, tendency for males in the majority or the minority to be perceived as influencing the group's decisions to a greater extent.

The earlier reported gender differences in influence could be due to the fact that this research was conducted a number of years ago when there was greater gender inequality in the business world and in society in general. Thus, the participants may have been more likely to gender stereotype than today's college students, who are exposed to a greater diversity of gender roles (Lottes & Kuriloff, 1994). Additional studies should examine if significant gender differences do exist in the 1990's. A study could be conducted in the workplace in which an older cohert of business personnel as participants to examine if differentials in influence exist among those actually in the business world.

The greater tendency for polarization in the last three scenarios reveals a potential problem with the methodology in the present (and other) studies. Although only lasting 20 minutes, the pattern of results is consistent with increased group cohesion over time. Yet this is markedly less than the interaction time spent in actual settings. Thus, differences in influencability between the genders and degree of polarization may not be as pronounced as what might occur in the real world of decision making, when the groups often interact for a longer period of time. It may become necessary to have the groups discuss a greater number of scenarios so they may influence one another over a greater length of time. .

Styles of influence clearly differed between males and females. Thus, there is a need for understanding its direct or indirect effect on male and female roles in decision making. With more women entering the upper-level management positions today, and with the use of diverse work teams making decisions and undertaking group projects, gender differences in influence and conformity must continue to be examined.

Scottish Soccer Violence and Religion

Megan O'Neill

Department of Sociology
Albion College
Albion, MI 49224

Faculty Advisor:

Len Berkey

The rivalry between regional soccer teams in Scotland can lead to violence, both around the field and across the nation. The two most prominent soccer clubs in Scotland are Celtic and Rangers, and these teams have religious affiliations which have led to a passionate rivalry between the fans. This presentation analyzes recent studies of soccer violence in Scotland and Ireland, incorporates a survey of Scottish University students and their attitudes towards this rivalry, and enhances the findings through interviews with Celtic and Rangers fans. The research indicates that the basis for this rivalry is not just in passionate team support nor is it solely due to sectarianism. The theory being proposed is that the soccer violence in Scotland between Celtic and Rangers is really a personification of deeply rooted hostilities of native Scots towards Irish (Catholic) immigrants over politics, economics, housing, education, nationality, and religion. It concerns one group's quest to establish an identity in Scotland and the majority's quest to keep them out.

BACKGROUND

For many Scots, The Old Firm rivalry means two things: soccer and religion. "The Old Firm" is the name given to the long standing association and rivalry between the Catholic-founded Celtic Football Club and the Protestant-founded Rangers Football Club and their respective fans. In the theory presented here, the sectarian argument that is used to explain this antagonism covers up many other integral components. It involves the old tale of Protestant vs. Catholic, but also majority vs. minority, native vs. immigrant, Unionist vs. Nationalist, and Northern Ireland vs. Republic of Ireland.

Celtic was founded in 1887 as a charitable organization to provide relief for the poor of Glasgow's East End. Brother Walfrid and Brother Dorotheus were the originators of the idea for a Catholic Irish soccer club. The official proposal was made on November 6, 1887, and in January 1888, a call was made for support for the new club. By May, the ground at Parkhead (an area of Glasgow) was ready after months of labor by volunteers and the first match was played on the 8th. The first game Celtic played and won was against Rangers later that month. They enjoyed continued success and within their first ten years had become one of the finest teams in Britain (Murray 1984:17-21).

Celtic has never had a Catholic-only signing policy and many of its players have been non-Catholic. Ireland is recognized as the spiritual homeland of Celtic, and in the early days the club had formal associations with the struggle for Irish Home Rule. All formal ties to Irish politics are gone now, but Celtic has "retained its religious character and its Irish sympathies, and remained inseparably linked with both" (Murray 1984:24-27, 60, 66).

Rangers was founded in early 1872 and played their first game in May. The club was started "by a group of lads from the Gareloch...attracted by the new craze on the Glasgow Green, they set out to found a football team." The team's stadium, Ibrox, was opened on its present site in 1899 in Govan, Glasgow (Murray 1984:12-17). The team did not knowingly sign any Catholic players until 1989, and this plus other actions of its administrators and players labeled it as a very Protestant-oriented club. A strong Unionist member, John Ure Primrose, first became identified with Rangers in 1887, and was elected a patron of the club in 1888. He had a very strong influence on the club and owned one of the two largest share holdings in 1899. "Primrose not only links Rangers to Unionism and anti-Irish politics, he was also a very keen, active and prominent freemason: an order which in Scotland has a strong anti-Catholic tradition... Leading members of Rangers had strong links with Unionism, freemasonry and Protestantism." (Finn 1991, pt.1:86-87).

Bill Murray states that just because of the religious affiliations the teams possessed, they were bound to experience hostility eventually. This is not the only theory as to when the sectarian troubles of The Old Firm began, however. Another theory mentioned by Murray is that the shipyard that was established by Harland and Wolff from Belfast in 1912 brought with it many Protestant workers to Glasgow. The area of the shipyard was near Govan, the home of Rangers, for whom many of the new workers began to show their support (Murray 1984:31, 59). It was also around this time that Rangers became associated with Ulster Unionist feeling. Celtic have always been proud of their Irish connection and since this was a particularly volatile time in the struggle for Home Rule, Rangers became a rallying point for Protestant Ulster and still are today (Moorhouse 1984:299). Irish political groups like the Orange Order and the IRA were starting to have followings in Glasgow, and the latter "aroused justifiable alarm among Protestants, particularly the working class of Glasgow; hostility to Catholicism and Irish nationalism, and what might have been seen as a defensive reaction to IRA militancy, found expression in a popular cultural sense through football" (Walker 1990:141, 143). Ireland was now showing its influence on both teams.

These ties to Irish politics and religious feeling are reflected very strongly in the teams' colors, emblems, and songs. Celtic has adopted the flag of the Republic of Ireland as its team flag and Rangers fly and wave the Union Jack of the UK. Celtics' colors are green, white and orange (gold) while Rangers' colors are blue, white, and red. These are also the colors of the flags of Ireland and the UK. Celtic fans wear scarves and other clothing with images of the Pope and shamrocks while Rangers use the Queen of England (the head of the Protestant Church of England) as their symbol. At games, Celtic fans sing about freedom from the crown, rebellion from religious oppression, there being "no Protestants at all," and blessing the Pope. Rangers fans sing about being up to their knees in Fenian blood, "f*****g" the Pope and the Vatican, and they call themselves Billy Boys after William of Orange (historical Protestant leader who beat the Catholics at the battle of the Boyne) (Murray 1984). The political connotations are abundant.

It was not by choice that the Irish community established its own clubs in order to participate in Scottish soccer. Scotland in the nineteenth century held strong religious and racial prejudices against the Irish, which limited their options in society. Social class divisions provided another barrier to the Irish. They tended to live among the lower classes and their work was largely unskilled. This low working class was excluded, sometimes deliberately, from many Glaswegian sporting clubs. Starting their own clubs was the only way the immigrant Irish could participate in Scottish sport (Finn 1991, pt.1:82-83).

Irish came to Scotland for many reasons, but especially for the new factories that were opening. Industrial growth in the western and central lowlands created many jobs as well as vacating the resident Scots from their agricultural positions which resulted in more labor demand. However, Scotland was largely a Presbyterian country and the majority of Catholics there were Irish immigrants. "In the co-existence of two populations competing for scarce resources and radically divided by religion, one has the basis for enduring conflict" (Bruce 1990: 232). Thus the friction between Catholics and Protestants in Scotland was not due to just religious and nationality differences, but also economic competition for employment.

The Irish also faced difficulties in housing and education. When the Education (Scotland) Act, 1918, was passed, Catholic Schools were given state support for the first time. In response to this, the Church of Scotland set up a committee to investigate this Act and the continuing immigration of Irish to Scotland. The committee reported on May 29, 1923 that the Irish were "a distinct 'race' whose presence was having a deleterious effect on the Scottish 'race' and Scottish culture" (Miles & Muirhead 1986: 120). Among the list of grievances against the Irish was that they were converting residential areas into Irish communities. First it was stated that the Scots desired to leave because "whenever the Irish population reach a certain proportion in any community, whether village, small town, or area of a great city, the tendency of the Scottish population is to leave as quickly as they can..." Then later the same report claimed that the Irish desired segregation. "The Irish have separate schools for their children; they have their own clubs for recreation and for social intercourse; they tend to segregate in communities, and even to monopolise certain departments of labour to the exclusion of the Scots" (Miles & Muirhead 1986: 121).

Whether the Irish desired separate housing or not, the fact remains that they were living in segregated communities and were being attacked for receiving the same financial support for their Catholic schools as the (Protestant) state schools. Many Scots did not like governmental aid for Catholic schooling and this added to the hostility between the two communities. It was seen as the next step by the Catholic Church to start its "destruction of the unity and homogeneity of the Scottish people" (Miles & Muirhead 1986:123). The segregation and paranoia that the Irish experienced in Scotland shows that they were the victims of racism. This racism was used to make a political issue out of Irish settlement in the late nineteenth and early twentieth century in Scotland. It is argued here that this treatment of the original immigrants is still shaping the experiences of their descendants and is finding expression today in The Old Firm rivalry.

The formation of Celtic brought with it a hope that the racism and discrimination that the Irish in Scotland had experienced could be ended when they were seen on an equal plain with the Protestant majority. The Irish clubs and their success, though well intended, were not welcomed, however. They were still seen as alien clubs and resentment against them became more pronounced as the conflicts in Ireland gained a greater place in Scottish and British politics (Finn 1994:47). Though the Irish in Scotland were doing all they could to establish a dual identity with Scots, the majority could not separate them from their homeland and would not accept them as fellow countrymen in any social arena. "True Scots would not support clubs of Irish-Scottish origins: truly Scottish clubs would not honour associations with another country" (Finn 1994:48). The Irish in Scotland, no matter how long they had lived there, were denied any claim on a Scottish identity.

Is there any clear definition of a Scottish identity then? As has been described earlier, religion plays a large role in Scottish life, but one that is very divided and turbulent. Though Catholicism is a minority religion, it has a strong following that makes its presence known in various ways, one of the most obvious being its soccer teams (e.g. Celtic). Another aspect of Scottishness is its history, but that too is not clear cut. Many inhabitants of Scotland are of Irish descent and claim to be Scottish as well. These are a minority but express their presence through football and other institutions (e.g. the IRA). A final defining aspect of a Scottish identity is a strong claim to *not* being English and this too, finds a declaration in sport. When the Scottish National soccer team travels to play abroad, the fans that go with them have become well known for their friendly and open attitude. A large part of why they do this is to differentiate themselves form the English fans who are portrayed as violent "hooligans." Thus, they are expressing not so much what they are, as what they are NOT (Finn & Giulianotti 1996:18-19).

Any claims to Catholicism or Ireland disqualify a person from an identification with Scotland. So, a Scot is not Catholic, not Irish, and not English. Unfortunately, it is difficult to find a clear definition of what a Scot *is*. Scotland has developed for itself a narrow, unyielding, sectarian identity that has come to be expressed in sport. Under the guise of religion and sport, soccer teams like Celtic and Rangers and their supporters fight and compete over many more deeper issues like nationality, politics, housing segregation, education, and employment. This narrow definition of what it means to be Scottish has created severe hostilities between people in its society that cannot be effectively released in any other way than soccer violence. A survey was developed to investigate this theory.

METHODS

The survey, written by this author, was administered to Scottish university students with the help of Dr. Christopher Wright at the University of Aberdeen. It had one section for personal data and then 14 statements about soccer, The Old Firm, religion in Scotland, their connections to Ireland, and the importance of these topics to the respondent. The choices provided were "strongly disagree," "disagree," "agree," and "strongly agree." Respondents were either allowed a week to complete the survey and return it, or were given a few minutes at the end of a lecture to fill it out.

RESULTS

The survey itself is too lengthy to be included here, but the findings will be described. The answers to the first four statements were in agreement with the theory proposed. The most frequent responses indicate that Catholics and Protestants do have problems with each other in Scotland, religion is a part of The Old Firm rivalry, and this rivalry is not a harmless thing. The answers to statements five through nine, however, were not in agreement with my theory since the respondents denied any ties to Ireland or Irish politics in The Old Firm. Responses to the last four items show that while the respondents themselves are not very interested in football, the country as a whole is. Religion also did not seem to apply very much to their lives or the team they support.

The responses to the items were cross-tabulated with the respondents' sex, religion, favorite team, and subject of study. These results can be seen in Table 1. Age, year in university, and nationality were not relevant to my investigation and therefore not considered.

Table 1: Significant results from Chi-square cross-tabulation

Statement Number	Variable in Tabulation	Result	Significance
13: "Football is a large part of your life."	Sex of Respondent	males: agree females: strongly disagree	.00012 (Pearson)
5: "Celtic is not a true Scottish team - it is more Irish."	Respondent's subject of study	Sociology: disagree Divinity: agree	.01956 (Pearson)
3: "There is nothing wrong with the rivalry between Celtic and Rangers."	Favorite team of respondent (Celtic or Rangers only)	Celtic fans: disagree Rangers Fans: agree	.08028 (Pearson) .04596 (Likelihood Ratio)

Even though there were 14 statements and four bases of comparison, only three Chi-square analyses were found to be significant at the .05 level.

The statistical analysis reveals that females do not have much interest in football, Divinity students see Celtic as being more Irish than Sociology students do, and Celtic fans feel The Old Firm rivalry is more problematic than do Rangers fans. However, the last two results are questionable. There were so few Divinity students (11.7% of sample population) that the second significant finding might be different if the numbers had been more balanced, and the last finding was only obtained by leaving out 82.2% of the respondents and considering only the 17.8% that listed Celtic or Rangers as their favorite team. This makes for very small numbers and an even more inaccurate sampling of the population. Females composed 61.9% of the sampled population, and if they do not care much about soccer, one wonders how much they know of the subject. Because the majority of the respondents showed this apathy, the rest of the findings are now questionable.

CONCLUSION

If the sample population had been more evenly distributed and larger, more accurate results would have been found. Although the survey did not entirely support the theory being investigated, the theory should not be discarded because the results may be a product of methodological problems. Soccer does play a large role in defining an identity for the people of Scotland, but more on divided, sectarian, and club-specific lines rather than on a national one. The Old Firm reflects these divisions and the quest for a Scottish identity of the immigrant Irish and their descendants, but The Old Firm is not the problem itself. A Scottish identity is still too narrow to allow all its people to feel welcome in claiming it. If the sectarian divisions in Scotland are ever to end and The Old Firm rivalry to cool its bitterness, the majority in Scotland needs to see immigrants and non-Protestants as equals and fellow Scots. The issue here is not about stopping the classic Protestant/Catholic fighting, but about making a minority group feel welcome to claim a Scottish identity.

A Content Analysis of Children's Television Commercials

Michelle E. Barton

Television commercials have been the subject of much research over the past few decades. This study attempted to analyze children's television commercials and the continued perpetuation of male dominance through commercials and narration. It was found that males still dominated as voice-overs, especially in mixed-sex advertisements, as compared to the research from ten and twenty years ago. In addition, there was a significant abundance of food-centered advertisements and repeated commercials in the sample as well.

BACKGROUND

Television commercials are extremely interesting to examine when looked at from a gender perspective. It is engaging to investigate gender roles and stereotypes perpetuated in commercials. Furthermore, it is apparent that the stereotypes and images portrayed on the screen have impact on the viewer; this impact is what most often stands out as important to analyze.

There has been a multitude of research conducted over the past few decades concerning television advertisements. More specifically, there has also been research which asserts that sex-role stereotyping and male dominance is perpetuated through advertisements aimed at children.

Male dominance in commercials was investigated in a study by McArthur and Resko (1975). Males were found to be the central figure in the commercials more often than females. Males were portrayed in more authoritative roles over females, and were also found to be more credible. In a study by Feldstein and Feldstein (1982), children's televised commercials were examined, from 1977 to 1978. There were significantly more males shown in commercials, but not more females shown. As expected, males and females were portrayed in commercials pairing them with sex-stereotyped toys. Accordingly, a content analysis of children's commercials was conducted, questioning sex-role stereotyping (Macklin & Kolbe, 1984). It was found that while most of the commercials were coded as mixed-sex (at least one male and one female in the commercial), males dominated as central figures and in voice-overs overall.

There has also been research regarding commercials for food and their effects on children. In one study (Galst & White, 1976), the effects of commercials and purchasing attempts in the supermarket were investigated. Results showed that children averaged about 2 purchase attempts (where the child attempted to persuade the parent to buy an item) for every minute in the store. There was a significant positive relationship between the overall television-reinforcement value and the total number of purchase attempts. Often times, children's attempts were for sugared foods, 68% for sugared cereal, for example. In a related study by Galst (1980), the effects of television food commercials and pro-nutritional service announcements as determinants of children's snack choices were examined. Results indicated that children in the control group chose sugared foods as snacks significantly more often than other control group chose sugared foods as snacks significantly more often than other intervention groups. After the intervention, it was found that having children in the no added sugar, pro-nutrition condition with positive adult comment was the most effective way to reduce the children's overriding selection of sugared snacks.

The present study attempted to analyze the content of children's television commercials, focusing more closely on male dominance and food-centered advertisements. The study also set out to investigate to what extent the commercials aired on television were repeated commercials. The reason for this content analysis was to see to what extent times have changed the way that gender images and dominance are portrayed through commercials, especially ones geared at children.

METHOD

Materials

A total of 248 children's television commercials were watched, taped from the three major networks and two cable channels. Commercials were taped in both the mornings and in the afternoons, on both weekdays, and on weekends. Service announcements were omitted from the sample, as were advertisements in which it was impossible to identify the gender of the narrator and/or the characters in the commercial itself. Service announcements were examined independently. The final sample was comprised of 203 commercials.

Procedure

The sample of advertisements was coded for the following variables: gender of the narrator in the voice-over, type of commercial (as a function of gender of actors), type of commercial (as a function of the product in the advertisement), and status as a novel or repeated commercial. For type of commercial (as a function of gender of actors), the advertisements were coded as either male (all males in the commercial), female (all females in the commercial), or mixed-sex (at least one male and one female in the commercial). All actors in the commercials were children. A repeated commercial was one that was coded at least once. The product was the targeted item being advertised in the commercial.

RESULTS

Chi-square analyses were conducted for all of the variables. The alpha level for all analyses was set at .05.

Narration

Of the 203 commercials coded, males dominated as the narrator 80.29% of the time, as compared to only 19.70% for the females. In the male commercials, males were the narrator 90.47% of the time. In the female commercials, females were the narrators 88.0% of the time, a slightly lower percentage when compared to males as narrators in the male commercials. Finally in the mixed-sex advertisements, males dominated as narrators 89.56% overall as compared to only 10.43% for females as narrators (See Table 1). After a two-way Chi-square analysis was performed, it was found that a significant difference for narrator as a function of gender did exist, $(2, N = 203) = 83.38, p < .01)$. Post-hoc analysis were performed, with two significant results found. Using Ryan's procedure, it was found that there were significantly more males as narrators when mixed-sex commercials were compared to female commercials, and when male commercials were compared to female commercials, $\chi^2 (1, N = 140) = 63.00, p < .05$; $\chi^2 (1, N = 88) = 47.25, p, < .05$.

Gender of actors

Of the 203 commercials watched, all were coded as being either male, female, or mixed-sex commercials. The male advertisements comprised 31.0% of the total sample, the female commercials encompassed 12.31% of the sample, and the mixed-sex advertisements subsumed the remaining 56.65% of the sample. The proportions for each expected frequency was based on the Macklin and Kolbe (1984) research. A Chi-square analysis was performed and a significant difference was found to exist, χ^2 (2, N = 203) = 17.74, p. < .01.

Table 1: Frequency (and Percentage) of Males and Females as Narrators (by type of commercial)

	Narrator	
Type	Male	Female
male	57(90.47%)	6(9.53%)
female	3(12.0%)	22(88.0%)
mixed-sex	103(89.56%)	12(10.44%)

Product type

Of the 203 advertisements viewed, 164 (80.78%) were for food, as compared to only 13 (6.40%) for toys. The remaining 26 advertisements (12.80%) were coded as other. A Chi-square analysis revealed that a significant difference was found to exist, χ^2 (2, N = 203) = 207.99, p < .01.

Novelty of the commercial

Of the total sample watched, 150 advertisements were repeated at least more than once. This comprised 73.9% of the entire sample.

DISCUSSION

The present study concluded that male dominance has continued to be perpetuated in children's television commercials, as compared to research from ten and twenty years ago. First of all, it was shown that males significantly dominated as narrators over females overall, especially in mixed-sex commercials. The present study's results were in concordance with previous research (Macklin & Kolbe, 1984), which showed a dominance of males as narrators during mixed-sex advertisements. Perhaps males dominated as narrators because they have often been portrayed as authoritative figures (McArthur & Resko, 1975). Based on these results, it can be posited that even in commercials geared at children, the idea of the male as the authority figure was perpetuated even twenty years later, in the present study. In the present study, males dominated as narrators significantly more when mixed-sex commercials were compared to female commercials, and when male commercials were compared to female commercials. Subsequently, it was shown that the results in this study paralleled those in the Macklin and Kolbe study (1984). Mixed-sex advertisements significantly dominated the total sample of all commercials watched; however, as compared to male-centered commercials, female commercials were extremely underrepresented. The abundance of male commercials over female ones did show a trend of under-representation of female commercials and an overrepresentation of male commercials.

In addition, the present study also found that there were significantly more food-centered commercials shown over the other advertisements in the sample. These results mirrored the results from the previous research (Macklin & Kolbe, 1984), but there was a larger percentage of food commercials in the present sample (80.78%). Along the same vein, the Galst and White study (1975) found that 68% of the purchasing attempts made were for sugared cereal alone, and a large portion of these attempts were successful. One might conclude that with more exposure to sugared food and junk foods, the more likely a child will be to attempt to consume that food. Considering that evidence points to the fact that pro-nutrition service announcements can help reduce sugar consumption in children (Galst, 1980), it was surprising to see so few service announcements for nutrition, but so many commercials promoting sugar consumption. Of the 164 food-centered commercials coded, 114 (70.0%) were for sugared foods or drinks, as compared to only 50 (30.50%) commercials for non-sugared food items. Finally, the abundance of repeated commercials should be considered. Of the entire sample, 74% were previously seen advertisements, and many of these were seen more than three times. It is also interesting to note that many of the repeated commercials were also for food items, and more often than not, food items with a high sugar content.

The present study attempted to analyze the content of children's television commercials. The present study provided some interesting and convincing data that demonstrate that there is still a strong presence of males dominating the authoritative role in commercials, especially in mixed-sex commercials. It is unfortunate that there seems to be little change regarding male dominance from 1975 and 1984 compared to the present time. Also, it seems as if children are being exposed to an extremely high number of food-centered commercials, many of which are for foods with a high sugar content and low in nutritional value.

A Critical Analysis of Current State Responses to the Problem of Child Maltreatment

Child maltreatment is a devastating social problem that lacks an adequate social response. Recent research statistics indicate that the number of abuse cases reported to Child Protective Services (CPS) is rising. Child abuse can result in many long-term impacts that can traumatize the abused child and generate negative influences within families, communities, and society at large. This research explores why attempts made by the child welfare system to alleviate child maltreatment have failed. Data was collected through an in-depth review of current literature. Findings suggest that the problems are multi-faceted and include: (1) unclear and inconsistent definitions used by "front-line" staff, administrators, and legislators, (2) structural problems within CPS, and (3) inadequate coordination between inter-governmental and private agencies. Based on these findings, recommendations concerning the elements of a more responsive system that can better guarantee the safety and protection of our children are provided.

THE SCOPE OF THE PROBLEM

Recent research data suggests that rates of child maltreatment in the U.S. are staggering and continuing to rise. According to the National Committee to Prevent Child Abuse (1995), in 1994, over three million children were reported as victims of maltreatment to state child protective service (CPS) agencies. This figure represents a 4.5% increase over the number of children reported in 1993 and a 330% increase from 1976 (Tower, 1996). Substantiation rates of child maltreatment cases are also rising. According to the U.S. Department of Health and Human Services and the National Center on Child Abuse & Neglect (1996), 1,012,000 children in 48 states were victims of substantiated abuse and neglect in 1994, an increase of 27% since 1990.

In 1994, an estimated 1,271 child abuse and neglect related fatalities were confirmed by CPS agencies. Approximately 45% of these deaths occurred to children who were known to CPS agencies as current or prior clients. Since 1985, the rate of child abuse fatalities has increased by 48% (National Committee to Prevent Child Abuse, 1995). Currently, more than three children die each day as a result of child maltreatment.

The physical and psychological consequences of child maltreatment are devastating. Research consistently shows that the impacts associated with abuse can be severe and long-lasting (Bensley & Meengs, 1996, Briere, 1992, Iverson & Segal, 1990, Tower, 1996, Wolfe, 1991). While children are affected by abuse in different ways, research findings suggest that maltreatment can impact all areas of functioning including the cognitive, socioemotional, affective, behavioral, and physical domains (Bensley & Meengs, 1996, Briere, 1992, Iverson & Segal, 1990, Tower, 1996, Wolfe, 1991). As a consequence, maltreated children are at risk for violence and delinquency, depression, self-destructive behavior, and suicide (Bensley & Meengs, 1996, Briere, 1992, Iverson & Segal, 1990, Wolfe, 1991). These devastating outcomes not only traumatize children but also generate negative influences within families, communities, and society at large.

OVERVIEW OF CURRENT RESPONSES

The Federal Child Abuse Prevention Act of 1974 (PL 93-247) established a general definition of child maltreatment and set requirements for states, including laws consistent with federal definitions, mandated reporting, and a CPS agency to respond to all reports of child abuse and neglect. In accordance with the Act of 1974, definitions used by federal and state legislatures have a tendency to be non-specific, describing only the phenomenon of child maltreatment. On the other hand, "front-line" staff use operational definitions, or specific sets of conditions, that outline possible indicators and consequences of child maltreatment (Iverson & Segal, 1990). The requirement of mandated reporting is responsible for the majority of reports now received by CPS agencies (Besharov & Laumann, 1996). Most states mandate professionals including teachers, school counselors, principals, law enforcement officers, mental health workers, hospital staff, private medical staff, and in some cases adults working with children to report suspected abuse (Pecora et al., 1992).

Every state CPS agency is designed to facilitate aid to children in abusive situations through casework intervention and treatment services. CPS agencies are only responsible for abuse or neglect occurring within the home due to parent or guardian actions. Any cases of abuse by strangers is conducted as a criminal investigation. Intake personnel in CPS agencies are responsible for the following duties: initial assessment and investigation, notifying law enforcement, risk assessment, and referral to caseworkers. Caseworkers complete the investigation, conduct a comprehensive family assessment, develop a case plan with the family, and follow-up with case management. The caseworker's main objective is to establish a service plan and to provide the family with assistance in following the plan. If the family does not voluntarily cooperate with the caseworker they can be court ordered to do so. Failure to comply with court orders results in the removal of the child. If the parents do not comply within an allotted time period, their parental rights may be terminated and the caseworker arranges permanency planning for the child's future (DePanfilis & Salus, 1992, Pecora et al., 1992).

Child maltreatment services fall into three categories: (1) CPS-provided, (2) community-based, and (3) family-based. CPS-provided services are managed by state agencies and include casework, foster care, parent aide, homemakers, adoption, and group homes. Community-based services, which may or may not be under contract with CPS, include guardian ad litems, public health nurses, child protection teams, parenting classes, drug and alcohol treatment, private counselors, and mental health centers. Family-based or home-based services are those which aim to keep the family unit together, avoiding unnecessary placement of children in substitute care. They also attempt to improve family functioning while eliminating the destructive behavior that led to the initial crisis. Examples of family-based services include therapy and concrete services such as providing toys, transportation, child care, clothing or food assistance, helping clients obtain employment, and arranging for financial assistance (DePanfilis & Salus, 1992, Pecora et al., 1992).

EVALUATION OF CURRENT RESPONSES

Due to inconsistencies observed between federal, state, and local agencies, there lacks a consensus as to precisely what constitutes child maltreatment (Bensley & Meengs, 1996, Iverson & Segal, 1990). While federal and state agencies use general definitions, "front-line" staff and social workers are guided largely by operational definitions. When federal and state laws and definitions conflict, social workers are put in a 'double bind' as to which goals take precedence in preventing and treating child maltreatment. Similarly, conflicting definitions impact mandated reporting rates in that many professionals either underreport or over report. Several factors may influence the decision to report including a concern for parental reaction and consequences for the child, confusion regarding what constitutes child abuse and neglect, worries about identity disclosure, and reluctance to attend court proceedings (Bensley & Meengs, 1996, Besharov & Laumann, 1996, Iverson & Segal, 1990, Reiniger et al., 1995). According to Reiniger et al. (1995), underreporting occurs because many mandated reporters lack knowledge of their legal obligations and the process of reporting suspected child maltreatment. However, Iverson & Segal (1990) state that there is a bias toward over reporting because mandated reporters may face criminal sanctions for failing to report suspected child maltreatment.

There are serious structural problems within the governmental CPS agencies mandated to handle cases of child abuse and neglect. Most state CPS agencies are large and bureaucratic, fostering ineffectiveness and a considerable lack of accountability. CPS agencies are protected by privacy laws, thus eliminating an internal system of checks and balances. As a result, they are not directly held accountable for the injuries and deaths that occur due to their ineffective efforts (Iverson & Segal, 1990, Pecora et al., 1992, Reiniger et al., 1995).

CPS agencies are governed by conflicting goals. The Federal Child Abuse Prevention Act (PL 94-237) requires that states prioritize family preservation. However, state laws require CPS agencies to protect the child. Paul Traus (personal communication, May 8, 1996), a former Deputy Secretary to the Washington Department of Health and Human services, believes that the primary policy dilemma of CPS agencies involves a balancing of family preservation and child protection Ultimately, CPS caseworkers must decide which goal takes precedence

Most CPS caseworkers are not trained in the social work roles, specific education and experience are crucial Likewise, to better address the needs of abused child and their families, caseworkers must engage in continuing education Presently, in-house training by state CPS agencies is insufficient to stay abreast of current issues Furthermore, CPS caseworkers are not afforded time to reeducate themselves (Roxanne Lowe, personal communication, May 17, 1996)

The predominant problem facing CPS caseworkers is extremely high caseloads Caseworkers average between 30 and 60 cases a week (Kaaren Jackson, personal communication, May 7, 1996) According to Pecora et al (1992), caseloads exceeding 45 per caseworker prevent any form of professional casework to be executed Given that CPS is mandated to respond to all reports, setting standards for caseloads is difficult Currently, there is not sufficient funding or enough caseworkers to meet the level of need According to Rick Winters, a Washington State CPS expert (personal communication, May 17, 1996), high caseloads force caseworkers to pick priorities and cut corners, taking away their ability to devote the necessary attention to each individual case High caseloads contribute to other complex problems for "front-line" staff including excessive time spent on documentation, an inability to investigate and assess all suspected cases, inadequate response times, high stress levels, excessive turnover rates, and a lack of communication with other agencies

Similar to CPS, prevention and treatment service agencies designed to facilitate aid to maltreated children and their families are plagued with a variety of problems First, there is a severe lack of communication and coordination between inter-governmental and private agencies Consequently, victims and perpetrators of maltreatment do not always receive proper care Additionally, the majority of existing services focus on residual rather than preventative care As a result, incidents that may be avoided through early intervention continue to occur Overall, these problems hinder the effective and productive delivery of services

ELEMENTS OF A MORE EFFECTIVE RESPONSE

In order to define and clarify the goals of the child protection system, it is necessary to determine a universally accepted operational definition of child maltreatment According to Iverson & Segal (1990), operational definitions based on knowledgeable factors and causes affecting the child result in the effective protection of children, which in essence should be the primary goal of all CPS agencies Using clear and precise definitions, laws, and goals also leads to educated reporting of suspected child abuse, therefore reducing the problems of over reporting and underreporting (Besharov & Laumann, 1996, Reiniger et al , 1995)

Structural problems within state CPS agencies must be addressed First, because caseworkers make critical decisions with limited information and time, it is extremely important that they be closely monitored and supervised This would lead to greater accountability (Pecora et al , 1992) Second, it should be mandatory for caseworkers and CPS staff to fulfill minimal educational and training requirements upon entry into state CPS agencies Similarly, caseworkers and other CPS employees need regular additional training in special areas and current issues These areas include cultural differences within the community, the relationship between child abuse and other prevalent social problems, and social work roles (e g intervention, interviewing, advocacy, mediator, and decision-making skills, etc) State CPS agencies should provide this training and also grant compensated time for their employees to pursue further education Finally, even with proper education and training, it is difficult for caseworkers to make effective decisions, assessments, and case plans when they are constantly beset by an unmanageable number of caseloads Reducing the number of caseloads may be achieved by hiring more caseworkers and increasing clerical support According to Kaaren Jackson (personal communication, May 7, 1996), a caseworker in Seattle, more caseworkers and increased clerical support within CPS would allow caseworkers to spend more time in the field, enhancing their ability to evaluate each situation separately, thoroughly, and more efficiently

BEST COPY AVAILABLE

In addition to remedying the problems within state CPS agencies, it is necessary to address the problems facing existing services geared toward abused children and their families. In order to ensure the effective service delivery, CPS-contracted, community-based, and family-based services should be coordinated at the state and local levels. According to Renee Toolson Doran (personal communication, April 26, 1996) of the Washington Council for the Prevention of Child Abuse and Neglect, services should be viewed as a web and improving the linkages between them will result in "catching more people." One method for creating more effective service coordination is to co-locate services. Co-location involves the housing of two or more entirely separate services under the same roof. Each service remains accountable to their respective agencies. Although co-location is not essential for effective service coordination, placing services in the same location would facilitate cooperation and accessibility to clients (Mark Ezell, personal communication, April 26, 1996).

Currently, most services are developed and implemented within the system only after a problem is identified. While there is a need to confront residual problems, efforts toward a solution must also focus on prevention. According to researchers, prevention services fall into two categories: primary and secondary. Primary prevention efforts include activities, services and programs directed toward the general population. On the other hand, secondary prevention includes activities, services and programs targeted to at-risk populations. Effective prevention utilizes both of these strategies (Pecora, et al., 1992). Overall, redirecting the focus toward prevention would produce many positive and long-term impacts, including a reduction in costly treatment services, and most importantly, the elimination of potential child maltreatment cases.

The majority of legislators in charge of allocating funds to programs do not believe that prevention is effective. In fact, there is little concrete evidence that many of the prevention and treatment services that currently exist are effective in alleviating the problems related to child abuse. Convincing legislators to fund programs without first demonstrating their outcome/effectiveness with empirical data is extremely difficult. In order to solve this problem, more outcome research on existing programs must be conducted. Government funding should be made available to agencies for this purpose.

In conclusion, these recommendations concerning the elements of a more responsive child protection system would better guarantee the safety and protection of our children.

ACKNOWLEDGMENTS

The authors would like to thank all of the individuals and agencies, who so generously donated their time to provide information and comments regarding the delicate issue of child maltreatment. The valuable input not only provided the basis of this research, but also influenced the authors' personal motivations to continue pursuing careers in the child welfare field.

The authors would like to express their gratitude to Matteo Ricci College for providing them with the opportunity to expand their horizons. The challenging program and high expectations continue to impact the authors' desire for intellectual development.

Finally, the authors would like to recognize their mentor, Dr. Madeline Lovell, for her continuous support throughout this year-long process. With her care and guidance the authors were able to accomplish more than they ever dreamed possible.

ABSTRACT

Academic dishonesty in college has increased to epidemic proportions over the past three decades. Perhaps competition for jobs and graduate school entry are partly responsible for the growing rates of academic dishonesty, but a consensus on the causes has not been reached by researchers. In addition, students are uncertain as to what behaviors constitute cheating inside and outside of the college classroom. While professors assume that students know and understand cheating policies, the students' views may differ from what instructors espouse. The current research assessed students' definitions and attitudes concerning academic dishonesty.

This study explored students' opinions of cheating behaviors using an experimenter-created Likert-formatted 25-item scale. The questionnaire asked students to rate the degree to which a behavior constitutes cheating by listing descriptions of behaviors related to plagiarism, outside classroom assignments, and giving/copying answers on tests. The students responded to the items using a 5-point scale where 1=strongly agree and 5=strongly disagree.

The sample of students participating in this study was drawn from a variety of courses at the University of Montevallo. Demographic data such as gender, age, and classification were collected to describe the sample and to use in the analysis of data. Data were analyzed with a factor analysis of the experimenter-created scale, frequency tables, and correlational analyses to facilitate future scale refinement.

Preliminary results indicated that while traditional "cheating behaviors," such as copying from someone else's paper during a test yielded an overwhelming majority of students(75%) rating the behavior as a clear example of cheating, but behaviors such as calling a friend about a take-home test were much less likely to be rated as clearly "cheating" (49%). These results will be used in a follow-up study to determine whether faculty and students' perceptions of cheating differ. Future research plans will focus on a comparison of faculty and students' views of behaviors constituting academic dishonesty. Such assessment will be useful in educational settings to enable professors to clearly define what they should stress to students concerning cheating policies, especially when assigning take-home assignments. Implications for future research are discussed, as well as additional applications of study findings.

INTRODUCTION

There is an increasing number of college students in the United States who are participating in an unfavorable and potentially career threatening activity, academic dishonesty. Whether it is referred to as academic dishonesty, academic misconduct, or cheating, the number of students who participate in this activity seems to be rising. One article reports that the occurrence of college academic dishonesty has increased from 23 percent to 75 percent from 1941 to the 1980's (API general info., 1996). While the percent of participators can be estimated, the exact activity or activities they participate in and with what frequency are unclear. To understand why academic dishonesty is increasing, a clear definition must be reached.

The majority of colleges have their own policy on academic dishonesty. However, the variations in the policies make it difficult to decide on a standard for defining academic

BEST COPY AVAILABLE

dishonesty The University of Montevallo, where our study takes place, states, "cheating is the giving or receiving of aid, whether written, oral, or otherwise, in order for a student to receive undeserved credit on work that is his or her own responsibility" (Fledgling, 1994-1995) The University of Alabama in Tuscaloosa stated specifics on what would be considered academic misconduct and direct penalties (Code of Academic Conduct, 1996) However, Lewis and Clark College states in its catalog that, "Academic dishonesty or cheating involves the use of any method or technique enabling a student to misrepresent the quality or integrity of his or her academic work (Academic Dishonesty 1995-1996)" It is hard to reduce the occurrences of academic dishonesty when policies, such as the one stated above, are so vague

A general lack of definitional clarity may be the cause of increasing numbers who cheat (Cheating, Hacking, and , 1996) The word "cheating" denotes a purposeful, unethical action, however there are people who "cheat" without realizing it This mostly occurs in out of class assignments where ideas of dishonesty vary the most There is confusion as to whether or not a group study session of brainstorming ideas for a paper, or exchanging interpretations of directions, oversteps "some ambiguous or undocumented" line of academic dishonesty (Cheating, Hacking, and ..., 1996) What may be seen as dishonest to faculty may be seen as much needed help and social interaction by students One recent study (Becker, Davis, Grover, McGregor, 1995) discussed academic dishonesty in terms of students internalizing ethical standards and stated that before students can apply standards, the schools and faculties should support these standards How can a faculty member support a standard when none is stated? How can students know they violate a policy when the definition is unclear or simply not there?

To help solve this definitional problem, we conducted a study to see how students define academic dishonesty Using an earlier study which analyzed students' perceptions of academic dishonesty (Doherty, Staik, Westcott, 1992), we created an instrument to be given to students now, and perhaps to faculty in a later study The instrument was based on a qualitative research analysis of students' responses to the question, "What constitutes cheating inside and outside of the classroom?" We identified categories which emerged from these responses and created a quantitative instrument representing these categories This instrument will allow us to assess the current views on academic misconduct and the differences between the ideas of upperclassmen and underclassmen It also will show us that upperclassmen will be more lenient than underclassmen on outside classroom misconduct

METHODS

Subjects

The subjects within the study are University of Montevallo students of Fall 1996 The gender ratio among subjects is as follows 26 males and 55 females In addition, there were 34 upperclassmen(Sophomore, Junior, and Senior) and 47 underclassmen(Freshmen)

Materials

In order to assess subjects' opinions of what is and what is not considered to be academic dishonesty, we have developed the Academic Dishonesty Scale, a questionnaire consisting of 25 questions The variation in questions consists of both in-class and out-of-class assignments in order to determine if students view them differently The method used to answer these questions is a 5-point Likert scale with 1= strongly agree, 2=agree, 3=neutral, 4=disagree, 5=strongly disagree Questions ranged from plagiarism to using crib notes during a test Other materials used include a general consent form, giving us the right to use the students' surveys in our study and a demographics page asking for information on the student's age, sex, race, religion, marital status, college major and minor, participation in a social Greek organization, and campus resident status

Procedure

We stressed the importance of the confidentiality of the students' answers to our survey and the special procedures we would be taking to ensure them of this confidentiality We informed them that the results would be available in the Psychology Office in May of 1997 if they want to know the outcome of our study

RESULTS

A principle component analysis was conducted on the Academic Dishonesty Scale as part of scale refinement procedures An orthogonal rotation of the items into two factors yielded factor loadings at the .4 level or above which could be used to define the factor structure. A factor loading represents the simple correlation (r) of the scale item with the hypothetical underlying factor.

Fifteen items loaded at the .4 level or above on Factor I. The content of these items identifies the most commonly accepted instances of academic dishonesty held by college students. The content of the top eight items with factor loadings of .92 to .82 involve cheating practices in which the student actively initiates the dishonest act. The items also include high profile actions that have severe punishment, such as plagiarism and looking at another person's test.

The remaining scale items with factor loadings of .76 to .50 have no commonalties that could be distinguished. The items dealt with a mix of overt, covert, classroom and outside classroom activities related to academic dishonesty, but by the strength of their relationship with Factor I indicated that the item content was valid.

Seven scale items loaded at .4 or above on factor 2. The items that loaded high on this factor were items that most students did not feel were representative of academic dishonesty. Four of the items deal with outside classroom activities which involve comparing/receiving test or homework answers through other persons or sources. The remaining three items focus on dishonest actions that do not involve a person's score on tests, homework, or projects. These final three items consisted of lying to a teacher, complimenting a teacher in order to try to influence a grade, and not reporting an incident of cheating that the student saw. The students do not see these activities in the same light as they see more active cheating behaviors. See Table 1 for specific item descriptions and loading on Factor I and Factor II.

Three of the scale items loaded at approximately the same level in both Factor I and Factor II. The content of these items involve: copying someone's homework, taking money for doing someone's work, and glancing at another paper and seeing something to jar your memory. See Table II for item description and loadings.

This research sample consisted of 47 (58%) underclassmen and 34 (42%) upperclassmen. The study indicates that on outside classroom assignments, upper and lower classmen generally have similar views. There are only three items where a larger percent of underclassmen were more lenient on activities outside of the classroom. These include: not carrying your weight in a group, discovering someone else's idea and using it as your own, and using answer keys when doing homework. See Table III for frequency data.

TABLE I - Items Loading on Factor I or Factor 2 at .4 Level or Above

Item #	Description	F1	F2
02	Cheat sheet	92	
09	Putting your name on someone's work	92	
01	Looking at a classmate's paper	91	
19	Selling copy of test	89	
07	Leaving test to get answers	88	
04	Paying someone to do your work	86	
14	Plagiarism	83	
17	Unequal work in group project	82	
13	Asking for answers with sign language	76	
18	Using teacher restricted sources	71	
12	Using someone else's idea	71	
21	Give answers with sign language	69	
03	Getting a copy of test	62	
08	Answering *here* for someone else	58	
15	Someone's research = Your benefit	50	
10	Brownnosing teacher		78
25	Getting help for take-home tests		72
20	Swapping answers among group		68
22	Lying to teacher		68
06	Using answer book to get answers		60
16	Not reporting seeing someone cheat		59
11	Sorority/fraternity test files		48

TABLE II - Items Loading on Both Factors at 4 Level or Above

Item #	Item Description	E1	E2
5	Copying someone's homework	50	43
23	Doing someone else's work for money	53	52
24	Glancing at a paper to jar memory	45	72

TABLE III - items differentiating upperclassmen from freshmen in frequency of response

Item #	Item Description	Freshmen%	Upperclassmen%
06	Using answer book/keys	51 06	29 41
12	Using another's idea	27 60	11 80
17	Unequal work in group project	29 70	14 70

DISCUSSION

The goal of our study was to assess University of Montevallo students' perceptions of academic dishonesty and to begin to form a working definition of the term "academic dishonesty" for our campus and student population From our factor analysis, we can determine the most commonly thought of instances of academic dishonesty in our sample It appears that the items in the survey dealing with widely known and severely punishable infractions such as looking at another's paper, having a cheat sheet, having/paying someone do homework for you, and leaving the test to get answers are those items that rank high on Factor I If an item scored low on Factor I and conversely high on Factor II, it was generally not considered as important to the students as representing academic dishonesty The items that scored low on Factor I were those dealing with outside classroom activities where people were working together (as opposed to paying or receiving money for work done) or dishonesty by omission, e g , not reporting someone else cheating It appears that it is more acceptable to share answers in group form with people who are taking the same class, than to pay someone to do work for you or put your name on someone's paper Also, lying to a teacher about why you were not prepared was more acceptable than using a resource that the professor told you not to use

In opposition to our original hypothesis, the results of our survey indicate that, in general, upper and lower classmen hold similar views toward outside-classroom cheating activities There are only three items that show a significant difference between the views of upper and lower classmen in relation to outside-classroom behaviors These items had a larger percentage of freshmen indicating on the survey that they did not think these items constituted academic dishonesty These results show that underclassmen are more lenient on such actions as using answer keys for homework, discovering another's ideas and using them as your own, and not carrying one's weight on a group assignment

We are proposing that definitions of academic dishonesty within colleges and universities be more clearly stated with specific examples of undesirable behaviors and their consequences given We feel that this will help erase the confusion of undergraduates as to which behaviors are or are not examples of academic dishonesty Once schools bring attention to these behaviors and students realize the repercussions they must face if they are participants, perhaps students will be less likely to rely on someone other than themselves in completing their academic work

Further research done on this subject assessing the attitudes of faculty in comparison to those of students will bring attention to the differences of students' and faculties' perceptions of academic misconduct This research would allow universities as well as faculty members to develop specific academic dishonesty policies in hopes of reducing the rate of academic dishonesty

It would be optimistic to think that simply clearly defining academic dishonesty would considerably lower its occurrence However, if a specific definition was combined with an emphasis on the benefits of being academically sound and the importance of learning for a lifetime, then students might decide not to participate in such a degenerating activity Although a university whose lax conduct policies might facilitate cheating, it is the students who make the choice whether to commit the crime or not A significant change will come about only if faculty and students together work toward the goals of honor and integrity

Academic Dishonesty Scale

For each item below, choose the number from the following scale which best represents your opinion

5 - Strongly disagree
4 - Somewhat disagree
3 - No opinion
2 - Somewhat agree
1 - Strongly agree

ACADEMIC DISHONESTY IS

1 ______ looking directly at another person's paper to copy an answer during a test
2 ______ using "crib notes" or a "cheat sheet" during a test or class assignment
3 ______ getting a copy of the test prior to taking it
4 ______ having/ paying someone do homework or at-home projects for you
5 ______ copying someone's homework
6 ______ using answer book or keys to get homework anwers
7 ______ leaving the test to go to the restroom/or another place to get answers
8 ______ answering "here" or signing someone's name when he/she is absent
9 ______ copying someone's paper or work and putting your name on it
10 _____ trying to influence a teacher to give you a better grade
11 _____ using sorority /fraternity test files
12 _____ discovering someone's idea and using it as your own
13 _____ asking for answers with gestures or sign language during an in-class assignment
14 ____ plagiarism of resource materials or documented work
15 _____ using someone else's research for your own benefit
16 _____ watching someone cheat without reporting it
17 _____ not carrying your weight in a group project for which everyone gets the same grade
18 _____ using sources on homework which the professor told you not to use
19 _____ getting a teacher's copy of a test to sell
20 _____ conducting group sessions to swap or check the accuracy of answers
21 _____ giving answers with gestures or sign language during an in-class assignment
22 _____ lying to a teacher about why you are not prepared in class
23 _____ taking money for doing someone else's work
24 _____ glancing at another paper and seeing something to jar your memory
25 _____ working with someone else on a take-home exam

Changing Pedagogy: Using a Computer Simulator to Teach Ethnographic Methods

Gregory R. Balza

Faculty Advisor
Manuel L. Carlos Ph.D.

ABSTRACT

Advances in multimedia computer technology have lead to changes in instructional pedagogy. Emerging from these advances is an Ethnographic Field Research Simulator (EFRS). The guiding principles behind EFRS has been to design a delivery system encompassing, ethnographic data, languages, culture, scientific and ethnographic methods, and the field into the classroom.

This study will focus on how students learn using EFRS, and the advantages of using a simulator versus learning ethnography from strictly reading books and attending lectures. My presentation will discuss how students learn ethnographic research methods, and the management of electronic data to write an ethnography.

INTRODUCTION

Within cultural anthropology, there is a wide abyss between acquiring an understanding of the nature of ethnographic field data, the pedagogy used to teach ethnographic field methods, and the execution of actual fieldwork. Although the discipline of cultural anthropology in the US and Europe has undergone several distinct periods, the process and manner in which ethnographic field methods are taught has changed very little (Johnson, 1990). Indeed it appears that the systematic teaching of fieldwork methodology has been conspicuously absent from graduate and undergraduate training programs. According to Alfred Kroeber, one of the founding fathers of anthropology, when asked some years ago by a then beginning professor of cultural anthropology, Charles Wagley, for advice on teaching field methods, Kroeber replied "Some can and some can't." (Wagley, 1983) This sink or swim approach to fieldwork, although a serious flaw in the programs teaching anthropology today, leaves room for changes and innovations in the planning, delivery of teaching ethnographic field methods, and cultural navigation. Fortunately, there appear to be some changes taking place that attempt to remedy this condition (Carlos, et. al, 1996).

Given the paucity of information regarding innovations in anthropological pedagogy (Russell, 1995) , and the disciplines' mystique about fieldwork; it is assuring to know that there are recent attempts to give large numbers of learners knowledge about the conduct of anthropological field methods and experience in carrying out ethnographic research. The purpose of this report is to describe the features and value from the point of view as a student participant of one such innovation. This innovation involves the use of ethnographically authentic and computer lab based simulations of field work.

METHODOLOGY

What would it be like to practice ethnographic field methods in Mexico's peasant villages without actually traveling there? Well, this past year approximately 45 students at two universities have had such an opportunity They are using, what Dr. Manuel L. Carlos, professor of anthropology in the Social and Behavioral Sciences Center at CSUMB and Professor Emeritus at UCSB calls, an Ethnographic Field Research Simulator (EFRS). I have been among those students using this learning package.

It is the first of its kind anywhere, which integrates scholarly content and multimedia into the curriculum. EFRS is on the forefront of changing educational pedagogy in American higher education. The virgin territory EFRS crosses will have long lasting implications in terms of the way ethnographic method and theory are taught, the mobility of higher education, and intellectual property rights issues.

EFRS is the result of over nine year's field research in Queretaro, Mexico. The Queretaro Research Project (QRP) is where the computer simulation idea began and was carried to fruition. QRP is a binational research project housed at the University of California, Santa Barbara (UCSB). Besides being at UCSB, this project works in collaboration with the University of Queretaro (UAQ), and is now being taught at California State University Monterey Bay (CSUMB). The project is supported by UCSB and the National Science Foundation (NSF Grant No. 9455699), Division of Undergraduate Education. Dr. Carlos began the project over nine years ago and it is ongoing.

EFRS is being beta tested at two campuses, UCSB and CSUMB. CSUMB, the newest campus in the California State University system is also seeking to make a mark in

BEST COPY AVAILABLE

higher education, with emphasis on technology, second language acquisition, commitment to multi-culturalism, and a global awareness; is well suited as a beta testing site. Instructors at CSUMB are given more latitude to be pedagogically innovative as compared to a more established institution (UCSB). Compare UCSB's Anthropology 111A: Ethnographic Data Analysis to CSUMB's SBSC 313 Learning Ethnographic Methods in a Multimedia Electronic Environment, the difference in course titles begins to describe the atmospheres at each institution. The culture of technology and experimental nature of the university make it an excellent choice to try something that has not been done before.

After several years of data collection by Dr. Carlos and his students, attempts were made to archive the data. The data was first digitized and then catalogued. Initially, an electronic searchable database was to be constructed. Working in a similar manner as current search engines do on the Internet, the database rapidly compile and produce "links" to the requested information. Although the projected began as a database, the notion of the simulator derived from how airplane pilots use flight simulators to teach prospective pilots how to fly an airplane. Basically, the same principle of introducing the concepts of flying an airplane are then applied to the teaching of ethnographic methods and fieldwork. Not only are the concepts introduced, but also so are building the requisite skills that are then necessary to fly an actual plane are then gained through practice.

Although, a simulation does not provide exactly the same sensation as actually flying a plane it does have validity for flight training. Similarly, EFRS provides students with conditions to practice ethnographic methods in a computer laboratory environment. Although, one could argue that the missing human factor nullifies the usefulness of EFRS, I will provide evidence derived from my experiences and those of other student's to the contrary.

A simulator such as EFRS is a device that enables the operator to represent under test conditions phenomena likely to occur in actual performance. This definition, according to Webster's Dictionary, implies the presence of a replication so well constructed that the product can pass for the real thing. When applied to the study of flight simulation or ethnographic methods, simulations can serve as suitable substitutes for the real thing. In a similar fashion, EFRS allows students a unique opportunity to practice ethnography without leaving the classroom and more properly the computer lab.

EFRS has several immediate contributions concerning teaching ethnographic methodology. First, EFRS introduces students to fieldwork, in an international setting, without the cost of travel to the field. On a related notion, students are taught that time and budgetary constraints are a part of the field experience. With shrinking budgets and the highly competitive nature of obtaining funds to conduct field research, it is not too early to have undergraduates thinking about the relationship between time and money.

Further, EFRS allows students to make mistakes without embarrassment or harm to the study population, while gaining research experience. Additionally, students can practice language skills while learning field methods and other patterns for living. Finally, students practicing fieldwork-using EFRS will not face the same situation as Kroeber's student did mentioned earlier in this paper.

Concepts of doing ethnography are introduced through lecture and augmented with supplementary information posted via the World Wide Web (http://www.monterey.edu/academic/centers/sbsc/sbsc313/index.html.) The content of these web pages provides background information and hypertext links to other sites of relevance. Not only do students receive additional information from a variety of sources, but also they are encouraged and have actively engaged other students in on-line asynchronous electronic discussions. The forum for this type of discussion is through newsgroups. Newsgroups are electronic "bulletin" boards where participants send and read messages, using currently available web browsers. A medium such as newsgroups differs substantively from email, because email arrives in your email account, whereas you have to seek the newsgroup.

METHODOLOGIES STUDIED USING EFRS

The developers of the simulator state that the purpose of EFRS it to introduce students to many of the dilemmas of ethnographic field research in a non-English speaking environment as well as in a non-US historical and cultural setting. (Carlos 1995) It is not intended as a substitute of a field experience or to be used instead of classroom instruction. It is an educational tool used to teach ethnographic methods.

The type of practice and assessment that EFRS provides is at the level that is most often introduced to first or second year graduate students. Though using the simulator is not the same as practicing ethnography in the field, it does offer many opportunities that will enrich an actual field experience. For example, students are not limited to using the simulator in class. In addition, students can repeat the exercises as often as their schedules will allow and add to their existing fieldnotes, field diaries and ethnographic reports. The concept of time and budgetary constraints are woven throughout the exercises, thus underscoring the importance of being prepared and understanding what types of data are sought. Students quickly learn that time and money is a fundamental issue when in the field.

Specific skills obtained though the use of the simulator are: (1) to collect observation and interview data, (2) conduct interviews, (3) record participant data, (4) take field notes, (5) analyze census data, (6) keep a field diary and write field reports. Additional secondary skills acquired are the ability to navigate in the regional culture of Queretaro, Mexico and surrounding communities, and to practice using the Spanish language. Exercises are available in Spanish and English, with many of the interviews are audible in Spanish and text translations are available in English.

Students can complete each of the seven simulated exercises and/or experiences at their own pace. Accompanying each exercise are a series of assignments and evaluation of the simulator and its contents. EFRS is designed to provide an introduction, but advanced undergraduates and graduate students can easily benefit from its use. The level of detail and analysis of the data is at the instructors' discretion.

ASSESSMENT

EFRS has built in evaluations that examine the content of the data and the effectiveness of the simulator. Students provide QRP with troubleshooting problems, suggestions and data on the effectiveness of the simulator. Qualitative responses are elicited from students rather than numerical because the simulator is being beta tested. The following skills can be practiced and evaluated using EFRS:

- the ability to take field notes;
- the ability to conduct simulated interviews;
- the ability to observe, and record what is being observed;
- the ability to keep a field diary;
- computer and Internet skills

The evaluation of the uses of electronic technologies in the enhancement of research methods teaching is assessed by:

- learning by doing
- presenting oral and written reports
- interacting with a research group
- distance learning
- analyzing ethnographic data
- communication with peers
- writing an ethnographic report
- categorization of collected data

FINDINGS

The initial findings suggest that EFRS has cost saving potential. Content analysis from student reports and feedback from state wide budget analysts indicate that EFRS is portable, can be easily used and introduces students to fieldwork in an international setting without travel. This is particularly valuable to student pursuing advanced degrees in the social sciences. Furthermore, it introduces students to the relationship of time management and budget. EFRS provides a baseline to track student progress. Each student can access identical data sets, and has the same resources to complete exercises and write ethnographic reports. Perhaps the greatest potential of EFRS is to provide opportunities for students to practice ethnography in the classroom, before they take ethnography to the field.

CONCLUSION

EFRS brings students into contact with an ethnographically accurate environment in which to conduct research and experience field work as ethnographers would. It also provides a readily accessible method and curriculum for teaching undergraduates how to do ethnography. The content of the simulator seems form a longitudinal study being conducted in Queretaro, Mexico. With subsequent models or versions of the simulator change over time can be analyzed, such as in the case of Robert Redfield's Tepoztlan and Oscar Lewis' Life in a Mexican Village: Tepoztlan Restudied.

EFRS allows students to learn the fundamental skills needed to carry out field work. Although one could argue, that instruction in ethnographic methods must include real informants, not videotape. Certainly, the human factor is critical in the field, but so is a low cost alternative for the purpose of practice. The technical skills students acquire based on systematic data collection methods, and discipline should prove useful in the field. In June 1997, approximately four students from CSUMB will travel to Mexico to find out exactly how well the simulator has prepared them for fieldwork in a Mexican peasant village. I will be among them. We will be gathering data the will augment data for Simulator 2, which focuses on Mapping, and Simulator 3, which focuses on Genealogy and Kinship.

Again, EFRS offers a low cost alternative going to the field, while providing a replication of life in a peasant village. It introduces the relationship that time and funding play in a research project. EFRS provides a baseline for students and instructors to use when assessing progress. In addition, no special computer training is needed to us EFRS, besides the ability to use a mouse. With rapidly changing computer technology and increasing global interdependence, tools such as EFRS will be on the forefront of changing pedagogy.

The Influence of Pretrial Publicity on Juror Decision-Making: A Meta-Analysis

Jasmina Besirevic

Department of Sociology
Augsburg College
2211 Riverside Avenue
Minneapolis, MN 55454

Faculty Advisor:
Nancy Steblay

High-profile trials in recent years have generated interest in the impact of pretrial publicity on a defendant's right to a fair trial. This project is a meta-analytic review of the research literature on pretrial publicity effects. Meta-analysis produces a statistical test of the complete data set, allowing conclusions about the overall status of a hypothesis across multiple tests of the hypothesis. At present, 15 studies have been found which test the hypothesis that negative pretrial publicity increases the likelihood of "guilty" verdicts by jurors. In support of the hypothesis, a significantly higher level of guilty verdicts occurred in subjects exposed to negative pretrial publicity, compared to control subjects, $Z_{re} = 11.23$, $p < .0001$. The overall effect size, $r = .17$, indicates a small effect across the studies. Additional analyses address moderator variables, such as type of publicity, while discussion focuses on the application of the findings to courtroom decision-making.

The news media--television, radio and newspapers--continually inform us of crime in today's society. The media cover dramatic crimes, focusing on attention-grabbing events and thereby bringing only the most sensational and bizarre crimes to the public attention (Conklin, 1992). It is not surprising then that people react to news of sensational crimes and their trials with a great fascination. For the society as a whole, trials are often seen as the essence of the drama and dynamics of the culture (Friendly & Goldfarb, 1967).

According to Carroll, Kerr, Alfini, Weaver, MacCoun, and Feldman (1986), the growth of print and electronic media has significantly complicated the free press-fair trial dilemma, putting a heavy burden on the trial judge who must balance the interests of both media and justice. The problem arises when potential jurors are exposed to and influenced by information prior to trial. The courts find themselves in the difficult position of maintaining the defendant's Sixth Amendment right to a fair trial without infringing on the Constitutional guarantee of freedom of the press (Otto, Penrod, & Dexter, 1994).

Information about the impact of pretrial publicity is necessary to the judge's decision-making. Researchers have traditionally used two common approaches for studying the influence of pretrial publicity: surveys and jury simulations. For example, research done by Nietzel and Dillehay (1983) provided the results of surveys for five murder trials. They found that a higher percentage of respondents in the venue counties had heard or read about the case, hence concluding that the possibility of bias would be greater in those venue counties than in other counties. Similar results were found in Costantini and King's research (1981) where respondents with greater knowledge about a case were found to favor the prosecution.

The second approach used to study the effect of pretrial publicity on juror decision-making involves the use of jury simulations which attempt to approximate the trial experience for mock jurors in a controlled experimental environment (Otto et. al., 1994). Following exposure to pretrial publicity, subjects are asked to evaluate video tapes of mock trials (e.g., Kramer, Kerr, & Carroll, 1990), a short written summary of trial proceedings (e.g., Sue, Smith, & Gilbert, 1974), or a reenacted trial (Dexter, Cutler, and Moran, 1992). Researchers have found that negative pretrial publicity increases conviction rates even for subjects who underwent an extended voir dire.

Although both surveys and jury simulations offer information, these methods are not without problems. Survey research suggests that pretrial publicity does influence the juror's decision about the verdict, however only the extent of exposure to pretrial publicity is assessed. At the same time, even though the simulation method enables the researchers to vary the types and amount of pretrial publicity given to subjects in the experiment, it does not always demonstrate clear effects for pretrial publicity.

Additionally, a number of studies (e.g. Greene & Dodge, 1995; Greene & Wade, 1988; Kramer & Kerr, 1989) suggest that certain types of pretrial publicity are more likely to create bias than other types. According to Otto et al. (1994), the American Bar Association (ABA) in 1968 identified a number of categories of pretrial publicity which

BEST COPY AVAILABLE

could compromise a defendant's right to a fair trial, including prior criminal record, statements about the defendant's character, reports of confession, statements from potential witnesses, and others. A summary of the research which would address these variables would be useful at this time.

In fact, Fulero (1987) argues that researchers have collected enough evidence about the effects of pretrial publicity that their findings can be used to address judicial concern about the influence of pretrial publicity. The purpose of this research is to determine the extent to which negative pretrial publicity affects juror decision-making. Fifteen studies have been located to address the effects which negative pretrial publicity has on juror verdicts. These studies examined similar variables and hence allowed application of the statistical procedures used in meta-analysis, specifically: (1) assessed the overall probability of a relationship between negative pretrial publicity and post-trial verdict, and the size of this effect; and (2) identified gaps in our knowledge and necessary areas for future research.

METHOD

Sample

Several steps were taken to locate potential studies, including a computer search of five abstract services, PsychINFO, SOCIAL SCISEARCH, FirstSearch, InfoTrac and Lumina. A manual search of relevant references cited in any of the previously located articles was performed. Finally, some authors of primary articles were contacted by electronic mail (e-mail) and asked to send any relevant works, published or unpublished. The final sample then included 13 published reports, one conventional paper, and one unpublished report each representing the unit of analysis of this research study. The articles were selected for inclusion in the review if the author(s) examined different levels of negative pretrial publicity with verdict as a dependent measure. For the purposes of this study, pretrial publicity was defined in either of two ways: (1) negative information about the character, credibility and reputation, or prior criminal record of the defendant (25 tests), or (2) negative information about the type of crime in general (4 tests). The final sample represented approximately 5,406 subjects.

Study characteristics

Various methodological and theoretical characteristics were recorded, including the source (published report, convention paper, or unpublished manuscript), author, date of the study (between 1974 and 1996), sample size, variable operational definitions (negative pretrial publicity as the independent and post-trial verdict as the dependent variable), specifics of research design, and statistics.

Statistical Analyses

According to Rosenthal (1984), an overall probability level associated with the observed pattern of results was calculated by combining Z-scores of individual tests of the one-tailed hypothesis. When unreported by the authors, Z-scores were calculated for each test by converting the statistical data reported in the original articles. The overall Z-score (Z_{ma}) provided an estimate of the overall probability level (see Appendix A).

The effect size is a statistical indicator of how large the relationship is between the variables. In this case, the effect size for each individual hypothesis test was the correlation coefficient *r*. In order to calculate the mean effect size, the summation of individual effect sizes was divided by the number of effect sizes reported (Rosenthal, 1984).

As mentioned earlier, a fail-safe *N* was calculated due to the possible selection bias in the studies. According to Rosenthal (1984), this method results in an estimate of the number of additional tests that would be needed in order to bring the significance level attained through the meta-analysis to a value larger than .05.

RESULTS

The 15 studies (29 tests) which dealt with the impact of pretrial publicity on juror decision-making yielded a Z_{ma} of 11.23 ($p < .0001$), indicating that subjects who were exposed to negative pretrial publicity were significantly more likely to vote for a guilty verdict ($N_{fs} = 1{,}323$).

The overall effect size for the 29 tests of hypothesis included is .17 [CI (95%) = .11 to .22]. Although this is a relatively small effect size it is still an important indicator of the influence of pretrial publicity since it is different from zero.

At the time of writing, the author is investigating moderator variables including

(1) the two approaches most common for studying the effects of pretrial publicity on juror decision-making, survey vs. simulation, and (2) the type of information about the defendant (general vs. specific to the defendant). Just two studies including five tests (Costantini & King, 1980/81, Moran & Cutler, 1991) used a survey. These five tests produced $Z_{ma} = 10.17$, $r = .39$; while the remaining 24 tests used simulations $Z_{ma} = 7.70$, $r = .12$. Twenty five tests included specific information regarding the defendant ($Z_{ma} = 10.86$, $r = .17$), while only four tests included general information producing $Z_{ma} = 3.09$ and $r = .13$.

DISCUSSION

This study was designed to test the extent to which negative pretrial publicity affects juror decision-making. Fifteen studies together offered survey research and jury simulations. The results demonstrate that negative pretrial publicity does affect juror decisions regarding defendant's guilt. Although the overall effect size generated ($r = .17$) can be judged as small (Cohen, 1988), it is relatively consistent across the studies as indicated by the confidence interval. Examination of moderator variables demonstrates significant Z_{ma}-scores when looking at either method used in the studies (survey vs. simulation), and both types of information about the defendant (specific vs. general). However, it is interesting to note that there is a larger effect size for survey studies. On the other hand, type of information (specific vs. general) produced similar effect sizes.

These studies suffer from methodological limitations, according to Linz & Penrod (1992). First, the subjects are not real jurors but often students or adults selected from voter registration lists. Second, the stimuli used in many studies may not be representative of real trials since the subjects have been exposed to selectively prepared and presorted videotapes of trials, written statements about evidence, or summaries of criminal proceedings.

However, the studies considered in this meta-analysis offer useful insights into the influence of pretrial publicity on juror decision-making. The research suggests that information about prior convictions and confessions, or emotional and sensational descriptions could be detrimental to criminal defendants. Jurors having knowledge of these facts through pretrial publicity may be biased against the defendant. A social psychological explanation of this bias is provided by the primacy effect. According to Zimbardo and Lieppe (1991), initial impressions of jurors form a mental schema, a biasing filter, through which subsequent information is selectively noticed and interpreted. In order to make decision about the case, jurors must form a mental representation of the event. The information first received will serve as a building block of the schema, thus the primacy effect will have an important impact on overall formation of schema. Therefore, when jurors receive negative information about the defendant, they then interpret subsequent information selectively and remember only what supports their initial impression.

In conclusion, the present study provides evidence that negative pretrial publicity has an impact on jurors' judgments of the defendant's guilt in a moderately realistic trial simulation and survey research. Future research should consider remedies for these effects, as well as additional moderator variables which may influence the results and remedies.

The question as to whether constitutional rights to a free press and a fair trial can be balanced is still present since the clash between the First and Sixth Amendments is still present. In order to address the problem it is necessary to employ powerful methods to capture pretrial publicity effects which influence juror decisions. According to Linz and Penrod (1992), there is a need for research with greater external validity that emphasizes a reliance on methods and procedures that both maximize experimental control and realism, and thus maximize both internal and external validity. These studies should seek to test empirically the social-psychological assumptions underlying the presumed effects of pretrial publicity given by the ABA in its Rules Code (Linz & Penrod, 1992). Furthermore, studies should be conducted to test the effectiveness of attorney strategies and judges' instructions for remedying the bias arising from exposure to pretrial publicity.

North America by Bus:
A Study of Interaction and Personal Space

Abstract

People engage in social interaction almost everyday. Whether this be through conversations, facial expressions, or merely eye contact, there are informal rules that guide their behavior. These rules also guide matters of personal spacing. On a Greyhound bus, the passengers are, for the most part, strangers to one another. Because of this, there is little clue to the background information of those around you. This lack of information causes the normal process of interaction to break down, and new informal rules become instituted and followed. Because of the limited amount of space designated to each passenger, the added factor of one's physical proximity to these strangers plays a part in the emerging interaction. By looking at both verbal and nonverbal communication, the rules become apparent and the ensuing interaction becomes patterned. This leads to the creation of new social worlds by those on the bus---worlds that are created from the shared experiences of the passengers. This research focuses on the way these new social worlds are developed and the manner in which the passengers engage in them.

Introduction

There have been a myriad of studies done on interaction between strangers, and some of these have concentrated on the arena of public transportation. Yet, nobody has conducted a study of cross-country or prolonged bus travel. This is an interesting area on which to focus because of the unique circumstances that arise on the bus---circumstances that become shared realities to the passengers on board. In the summer of 1996, the author took the Greyhound bus to more than thirty states in order to see how interaction was initiated, and then how it was either encouraged or ignored. The manner in which passengers negotiated their personal space within the context of a small amount of public space was also a subject of interest.

Methodology

The only way to do this study was through participant-observation, because there was no other way to gauge the involvement of the passengers except to actually be one of them. Ethnography and participant-observation were the best methods for this research because they enable one to watch as styles of interaction become patterned, and to then study the subsequent social worlds that develop from this. Doing this research as a Greyhound passenger can provide one with the chance to observe not only how people interact with each other, but also how they react to those who behave outside the norm. Furthermore, any observed anomie reinforces what the norm is, which enables one to focus on the specific behavior that is valuable to the research.

By taking fieldnotes during the trips, it becomes apparent that there is a certain pattern that arises on the bus. This paper will be able to concentrate on only a small piece of this pattern and it will draw primarily from the works of Erving

Goffman and Edward T. Hall. Using the theories of Goffman and Hall, this paper will examine how one chooses a seat and the significance behind that choice.

Theoretical Background

The least involved type of social encounter can be seen in the form of "civil inattention." Goffman (1963) explains:

> What seems to be involved is that one gives to another enough visual notice to demonstrate that one appreciates that the other is present (and that one admits openly to have seen him), while at the next moment withdrawing one's attention from him so as to express that he does not constitute a target of special curiosity or design (p.84).

This latter point is important in understanding an individual's stance when among strangers. By showing others the courtesy of civil inattention, one is claiming that he or she has no reason to fear, suspect, dislike, or want to avoid an other; and through this hopes to ensure that he or she will be treated likewise. One also finds that the need for civil inattention becomes stronger if the individuals are close to one another in proximity; and, conversely, the further away one is, the more license one has, for example, to stare.

An infraction of civil inattention is staring. A good example of this is when one is caught staring at another who was unaware that he or she was being scrutinized. At this point, the offender will either look away with some amount of embarrassment or try to cover it up as the "normal" process of scanning one's environment. Goffman (1963) sees staring as a form of social control. He believes that this is a common means of negative sanction and that it is often the first warning the offender receives that he or she is not following the proper norms.

Out of civil inattention comes the capacity for what Goffman (1963) calls "focused interaction" or an "encounter":

> An encounter is initiated by someone making an opening move, typically by means of a special expression of the eyes but sometimes by a statement or a special tone of voice at the beginning of a statement…The engagement proper begins when this overture is acknowledged by the other who signals back with his eyes, voice, or stance that he has placed himself at the disposal of the other for purposes of mutual eye-to-eye activity (p.91-92).

Thus an encounter usually begins with prolonged eye contact. This ritual can happen almost simultaneously, as when two people glance at each other at the same time. When this occurs, neither can be seen as the initiator, and therefore, neither can feel rebuffed if the engagement does not take place.

Mutual eye contact makes up the most common type of interaction between strangers: "Eye-to-eye looks, then, play a special role in the communication life of the community, ritually establishing an avowed openness to verbal statements and a rightfully heightened mutual relevance of acts" (Goffman, 1963, 92). Avoiding someone's eyes sends the message that no contact is desired. The lack of eye contact alone is often enough to keep communication from establishing because it avoids the "cooperative claim" that the seeker is trying to initiate.

Once the encounter has begun, eye contact must be maintained in order to make the participants feel they are truly engaged. That is, eye contact is often used to gauge how involved the participant is in the conversation. As in the initial avoidance, lack of or lessening of eye contact can be taken as a sign that the other wants to disengage from the encounter. If the participants are fully involved in the encounter, the subject matter at hand becomes their main focus and all attention is given to the conversation itself.

Results

Finding a seat on the bus was probably the most stressful part of the trip, especially when boarding a bus that was already full of passengers. The best way to see one's seating options was to get stuck behind someone trying to put their luggage in the overhead rack. This gave the new passenger time to look around the bus and see any empty seats. If there were no empty seats, the passenger could use this time to "size up" the other passengers and decide which people looked like acceptable seat partners. Goffman (1971) gives an example of the time one stops to pay the fare on a city bus as being used for the same purpose. Lyn Lofland mentions in her book, *World of Strangers* (1973), that Americans do not feel comfortable "taking a reading," which makes the need of a *reason* to stop even more important. If the bus was full, the game of "choosing" a seat begins. Goffman (1971) would call the bus seat a "stall;" it is public and meant to be shared, but would often be guarded by the first one there as completely his or her own. The easiest way to keep one's stall to oneself is through the use of possessional territory. Simply put, place your bags, your jacket, or any "personal effect" on the seat next to you and stare out the window. By doing this, the passenger was "marking it for his own and obliging competitors to move (or ask to have moved) something that symbolizes another" (Goffman, 1971, 34).

The avoidance technique employed most often on the bus was that of refusing eye contact to those seeking it. Merely making eye contact opens up an individual for interaction of some kind. When a new passenger was seeking a seat, any mutual glance could be taken as a sign of welcome. This "principle" was understood to some extent by nearly all of the passengers. Thus, by staring out the window, focusing on a book, or avoiding eye contact in some other manner, the seated passenger could successfully discourage new passengers from inquiring about the availability of the seat. Making eye contact could be taken as a sign of permission to be seated, and many passengers feigned sleep when new passengers were boarding, further discouraging any interaction.

Other passengers, however, would stare directly at the new arrivals. This method also proved to be effective, especially when the passenger was able to manage his or her face in a way that showed that no seatmate was desired. That is, many were able to make their faces expressionless, except for the glare in their eyes. It was rarely an outright look of anger, but more of a "don't even think about it" look that effectively warned new passengers that they were not welcome. It soon became apparent that this method was used more often on buses that were extremely crowded. At these times, even passengers who already had seatmates would glare at the new boarders in an unfriendly way. This seems to be a direct result of the discomfort passengers felt at having to compromise large amounts of what they considered their personal space.

The choice of a seat partner (when it actually was a choice) seemed, in most cases, to be based on a certain set of criteria. Often, people of the same ethnic background appeared at ease approaching one another (see Goffman, 1963, 131). However, this did not hold true for Anglo-Americans. Instead, approachable conversation partners seemed to be based on the old cliché of judging a book by its cover. Lyn Lofland (1973) calls this criteria "appearential ordering," which is categorizing people through visual clues like dress, hair, age, etc. (p.27). Good examples of this would be the way older women tended to sit with each other and also the manner in which "college-looking" people tended to group themselves together toward the back of the bus.

In *The Hidden Dimension*, Edward Hall (1966) discusses the concept of personal space, which is best defined as an invisible boundary around one's body that cannot be crossed without

BEST COPY AVAILABLE

provoking some reaction. Hall believes that these reactions are culturally learned, and this research will be concerned only with those considered "normal" in a Western paradigm (i.e. the United States). The reaction to an intrusion of one's space relies mainly on the relationship between the intruder and the intruded; it seems far more acceptable, even desirable, for one's lover to cross the line than for a complete stranger to do so. However, it is important to note that certain circumstances allow for acceptable boundary crossing (such as when one goes to the doctor), but this does not necessarily mean that these situations are any more comfortable, regardless of their validity. Individual reactions to the invasion of personal space usually include discomfort, anxiety, anger, or arousal.

Throughout his book, Hall gives examples of the ways in which people react to intrusion of their personal space. While his theories reinforced the findings of this study, they also had to be expanded to include the fact that the bus is a small amount of public space on which the passengers are continuously trying to negotiate their private space. Once seated, the negotiation of personal space became a never-ending battle for both of the passengers. What area technically belonged to whom had to be worked out tactfully and non-verbally.

The fixed seating on the bus is designed in a way that forced strangers to be within close personal distance of their seat companions; one could see, hear, smell, and feel the stranger. When they did have to share a row, the close physical proximity between strangers often caused anxiety and discomfort to the passengers. The close personal distance is one that is usually reserved for people who like each other, or at least know each other. On the bus, none of the normal starting points or mechanisms were there---strangers were forced into close proximity in an already confined setting. This proximity to strangers encouraged the development of strategies to bring some sense of order or comfort into an uncertain environment. When faced with this situation, passengers either tried to avoid interaction altogether or, conversely, seemed to feel compelled to talk to their seat companion. In the first, the passenger would become rigid and try to maintain his or her personal space through extreme body maintenance, such as turning one's body away from the intruder as much as possible. The focus here was on discouraging conversation, so any eye contact or touch was avoided. The second reaction was the exact opposite. The passenger seemed to feel the need to be engaged in conversation with the other as a way of feeling comfortable. In this situation, it appeared that the passenger was trying to make the situation "normal": he or she realizes that this distance was for close friends and therefore engaged in conversation because this is what one would normally do in this zone.

Conclusion

Seating on the bus led to close physical proximity between strangers. How people expected space to be used often caused anxiety and discomfort to the passengers who found themselves sitting with such strangers. When faced with this situation on the bus, passengers usually tried their best to keep their stalls to themselves, either by avoiding eye contact or, conversely, through staring. If this did not work and the passengers were forced to share "their" row of seats---their space---they would either try to avoid interaction altogether or, conversely, they seemed to feel compelled to talk to their seat companion. Both strategies were ways for the passengers to gain control of their social surroundings. These techniques were ways for the passengers to feel comfortable in a situation that they could not control.

ABSTRACT

For several decades, researchers have reported that the attitudes of young adults toward the aging population vary. These positive, negative, or mixed attitudes are based on the prejudices and stereotypes held by the young adults and possible personal experiences with aging adults (Cavanaugh, 1997). Most research has focused on the young adults' views of aging adults over 65 and not on the young adults' views of their own aging process. As people grow older, they must learn to deal with various losses, such as loss of health, loss of job, and loss of family members (Barrow, 1996; Cavanaugh, 1997; Ferraro, 1990). Older people also face diminishing social roles due to these losses. The observance of these role losses and changes may contribute to the stereotypes held by young people. Several studies (Collins, 1991; Generations, 1993; Gilbert, Cobern, & Staik, 1989) found that young adults hold both positive and negative stereotypes of aging. Positive stereotypes tend to focus on personality traits while negative stereotypes tend to focus on physical traits.

In the present study, we were interested in assessing the perceptions of college students toward the social aspects of their own aging. We developed a scale on a criterion-referenced basis from an extensive review of college level aging texts and their contents. The Likert formatted 20-item scale consists of items relating to one's own aging. Response choices are as follows: 1= Does not bother me at all, 2= Bothers me somewhat, and 3= Bothers me a great deal. The scale was administered to two college courses in the Fall of 1996. The scale, as well as a demographics form, was administered to 83 psychology students at the University of Montevallo in the Fall of 1996. The participant responses show that college students experienced high levels of concern about all aspects of aging, but that concerns surrounding the social changes inherent in the aging process were reported as the most disturbing. For example, students responded to an item about diminishing night vision and its effects on night driving for older adults, with 36.1% reporting that it did not bother them at all, 34.9% reporting that it bothered them somewhat, and 28.9% reporting that it bothered them a great deal. This finding contrasts with the pattern of responses found for social changes, such as with an item involving loss of close emotional / social bonds in the last years of life: only 6% reported that it did not bother them at all, 20.5% reporting that they were somewhat disturbed, and 73.5% reported that it bothered them a great deal. This latter pattern was typical throughout the items related to social changes, while the "vision item" pattern was noted for the physical changes related to aging. Future directions for research and applications in the classroom are discussed.

INTRODUCTION

For several decades, researchers have found varying attitudes of young people toward aging that are based on stereotypes and/or personal experiences of the individual. The purpose of the current study is to assess the attitudes and feelings of college students at the University of Montevallo toward various aspects of their own aging with a specific focus on social interaction and relationships.

Young adults often foretell their own life course by "perceiving" the courses of others (Erikson, 1987). Erikson (1987) wrote, "In cultures where to become old makes sense, there is a definite perspective on the whole of life. In our country, for most young people, the idea of becoming old and unable to advance further represents a questionable future." Undoubtedly, young adults are affected by what they observe from aging adults.

As people grow older, they must learn to deal with the various losses that begin to occur. Several researchers (Barrow, 1996, Cavanaugh, 1997; Ferraro, 1990) have found the losses of older people to include loss of health, loss of job, loss of independence, and the loss of spouse, friends, and family members. Older people also face diminishing social roles. Individuals "relinquish" many roles of adulthood by the time they reach old age and experience a decline in "societal significance" due to the loss of these roles (Cavanaugh, 1997). Work is one of the most important roles given up because one's job reflects how the individual is viewed by others and the individual's personal view of self (Cavanaugh, 1997; Ferraro, 1990). Nevertheless, the roles of older people are not completely lost, although these roles may change. For example, an older adult may be faced with raising grandchildren or caring for a surviving parent (Barrow, 1996).

Due to these losses, as an individual ages, he or she begins to depend more on family members for interaction (Schaie, & Willis, 1996). According to a number of researchers (Barrow, 1996; Ferraro, 1990; Schaie, & Willis, 1996), this is especially true when one loses a spouse. A newly widowed person often experiences loneliness during this time. Therefore, the older person may turn to other family members for help in fulfilling the needs once met by the spouse. Although these needs cannot be met by surviving family members, the remarriage of older people for this lost companionship is often discouraged (Barrow, 1996). Reasons for this discouragement include that many widows will lose the monthly benefits left by the deceased spouse if they remarry. A second factor is the discouragement of children who do not want the surviving parent's assets to go to the new spouse when death occurs. Another factor is the reluctance of the older person to remarry out of respect for the deceased spouse (Barrow, 1996). And so, all of these role losses and changes are observed by young adults.

Many studies have been conducted to assess the attitudes of adults toward aging. One study conducted in a southwestern community surveyed attitudes of adults, whose ages ranged from 18-92, toward aging and found positive and optimistic views about aging. Subjects agreed that they look forward to getting older, do not mind aging, and can control what happens to them as they get older. Subjects denied being afraid of getting "old," feeling that it is sad to get older, and feeling that older people are very boring and do not do much. However, they did agree that older people depend more on others and disagree that life is easier for older people (Harris, Page, & Begay, 1988).

Another view held by young adults emerged in several studies by Collins (1991) that found these adults hold both negative and positive expectations about aging. The first study by Collins found that subjects viewed their own (future) old age positively--more positively than their description of other older persons. A second study followed up by having subjects make predictions about their old age on a range of dimensions including social satisfaction; these results showed positive expectations with a bias in favor of self. The study by Gilbert, Cobern, and Staik (1989) and a study printed in Generations (1993) both found that American college students in class exercises typically characterize "old people" in terms of both negative and positive stereotypes. The negative stereotypes include physical traits such as "slow" and "feeble." Positive stereotypes tend to focus on personality traits like "sweet" and "caring." These positive traits are typically passive, viewing older people as "pleasant" and "storytellers." When asked to describe a particular older person, students generally wrote positive portrayals, often about healthy, active individuals. They tend, however, to think of these older people as exceptions to the rule, rather than changing the "rule" or their views of older adults. Gilbert, Cobern, and Staik (1989) also concluded that the number of positive descriptors of older people given by college students decreases as the age of the older person increases. These stereotypes may contribute to the attitudes and feelings of young adults toward their own aging.

These stereotypes may be part of the reason why the study done by Heckhausen and Baltes (1991) found that groups of young and middle-aged adults believed that aging-related increases in undesirable attributes were relatively less controllable than what the older adults believed. It seems likely that this view may have evolved from the negative stereotypes of aging. Collins' (1991) study results also suggest that previous research emphasizing attitudes toward and reactions to institutionalization painted too negative a picture of young people's feelings toward old age. Older adults may be less likely to endorse such a negative stereotype because of personal experiences that modify their views of aging (Heckhausen & Baltes, 1991).

The above research shows the variety of attitudes of young adults toward aging. However, the current study assessed the feelings and attitudes of young adults toward their own aging, not aging in general.

METHOD

Participants

The participants in the current study consisted of 83 students enrolled in two psychology courses at the University of Montevallo during the Fall of 1996. Subjects represented the age range of 18 to 47 with the mean age being 22 years. There were 61 females and 22 males.

Materials

A 20-item experimenter created, Likert scale questionnaire was used consisting of items concerning the attitudes toward one's own aging with response choices as follows: 1=Does not bother me at all, 2= Bothers me somewhat, and 3= Bothers me a great deal. Sample items on the questionnaire are:

"When older people no longer feel useful in a work setting, they feel depressed and worthless."

"Older people have a smaller number of friends unless they live in places where the proportion of older adults is high (e.g., retirement communities, public housing)."

"Many older adults have experienced the death of their spouse/partner."

"Because of vision changes which cause older adults to have difficulty in glare from oncoming headlights, they tend to decrease night driving."

Procedure

The students signed a consent form, filled out a demographics form, and completed the questionnaire. The above forms were placed by the students in envelopes to insure anonymity.

RESULTS

A principle components analysis was conducted on the questionnaire as a part of scale refinement. An orthogonal rotation of the items into two factors yielded factor loading at the .4 level or above, which could be used to define the factor structure. A factor loading represents the simple correlation (r) of the scale item with the hypothetical underlying factor.

Fourteen items loaded on factor one. The content of the items loading on factor one suggest a pattern of concerns about general major age changes. Six items loaded on factor two. The content of these items suggest a pattern of concerns about death and traumatic loss. See Table I for presentation of scale items used to define factors one and two.

Table I: Attitudes Toward Social Changes Due To Aging

Scale Item Number	Description	Factor I Loadings	Factor II Loadings
07	fewer new friends	.81	
11	fewer friends, in general	.78	
10	increase losses of loved ones	.72	
16	retirement / fewer friends	.66	
20	relying more on family	.65	
01	fewer relationships	.64	
03	death of parents		.64
05	discouraged from dating	.63	
06	no work / depressed		.63
13	loss of driving	.62	
14	hearing changes	.62	
18	without close family ties	.61	
08	death of sibling		.59
17	vision changes / driving	.54	
04	financial dependency	.53	
19	time in nursing home	.53	
15	death of partner		.50
12	death of children		.44
09	not in own home	.43	
02	divorce		-.36

DISCUSSION

Past research focused on young adults' views of aging adults over 65. The Attitudes Toward Social Changes Due To Aging scale was developed and used at the University of Montevallo to assess the perceptions of young adults toward the social aspects of their own aging. Results of this quantitative research effort indicated that young adults experience high levels of concern about all aspects of aging, but that concerns surrounding the social changes of the aging process are the most disturbing. For example, students responded to an item about diminishing night vision and its effects on night driving for older adults, with 36.1% reporting that it did not bother them at all, 34.9% reporting that it bothered them somewhat, and 28.9% reporting that it bothered them a great deal. This finding contrasts with the pattern of responses found for social changes, such as with an item involving loss of close emotional / social bonds in the last years of life: only 6% reported that it did not bother them at all, 20.5% reporting that they were somewhat disturbed, and 73.5% reported that it bothered them a great deal.

Although males and females responded very similarly on virtually all items, there are a few exceptions. For example, an item about society's discouragement of older adults dating and "falling in love" showed 18.03% of females responding that it did not bother them at all, 18.03% responding that it bothered them somewhat, and 63.93% responding that it bothered them a great deal. However, males responding to this item showed 22.73% were not bothered at all, 40.91% were somewhat bothered, and 36.36% were bothered a great deal.

While further refinement could lead to greater certainty about the validity of these subscales, the preliminary analysis suggests that the factor patterns discussed are quite appropriate. This result is not surprising since the Attitudes Toward Social Changes Due To Aging questionnaire was developed on a criterion-referenced basis from an extensive review of college level aging texts and their contents.

The findings of this study could be used by other researchers to learn more about the attitudes of young adults toward the social aspects of their own aging and to expand the study by assessing how different age groups feel about this topic. This research would also be useful in the classroom when discussing the aging process, what is "normal," and what the implications for students and education in general are.

Exploring the "GenderedPerspective" in Early Adolescents' Interpretations of Popular Music

Anastasia M. Pharris-Ciurej and Kristine M. Ward

Department of Sociology

Faculty Advisor:

Dr. Jodi O'Brien

Our research question focuses on young people and popular music: it was bourn of an interest to further explore the early adolescent stage of gender formation and adherence to popular culture combined with common allegations in the social arena that popular music lyrics adversely affect listeners.

Music lyrics have been the object of criticism for much of the last four decades, during which time, references to sex, violence, and drugs have increased (Took and Weiss 1994). Although concern for the messages that popular music is sending to its listeners has remained present over the years, surprisingly little research has been done on the effects of listening, particularly in the role of gender messages portrayed. Most study, attention, and regulation has been directed toward extreme songs not aired on the radio; many of these are from heavy metal or hard core rap music categories.

Because of studies done by music researchers Peter Christenson and Peter De Benedittis (1986), which state that early adolescence is a time of increased hours of radio listening and preference for "Top 40" hits, we chose to focus our examination of children's interpretation of music lyrics on mainstream, popular music. Studies done have estimated that one-third of fifth and sixth graders listen to the radio for two or more hours per day; others report afternoon radio listening among 83 percent of fourth and fifth graders (Christenson and De Benedittis 1994). Radio is a form of media that children listen to avidly during early adolescence; radios are cheap, portable, and accessible to children of all ages. 68% of fourth and fifth graders have a radio in their bedroom. Radio listening among early adolescents, unlike television viewing, occurs primarily away from the presence of adults. With estimates of between 71 and 92 percent of radio listening occurring while young people are alone, with friends, or with siblings, radio is very much a medium that is self-regulated and defined (Christenson and De Benedittis 1994).

While it is no doubt that radio and popular music are very common among children entering the stage of early adolescence, the extent to which those messages are heard and how they are understood remains unclear. Messages conveyed in the media about popular culture and adulthood are particularly important at this stage of young people's gender and social role development. Genderization, the process of identifying self with gender, begins to occur in early adolescence. This is a crucial period of time in which a person's interactions with their surroundings, messages of parents, peers, teachers, and media outlets formatively shape what a young adolescent identifies as female or male and how to incorporate those roles into the formation of their own ideas and actions of gender.

Perhaps more important for children in early adolescence is a myopic desire to fit in with peers who willingly or unwillingly imitate and circulate media messages through play and discussion of favorite movies, T.V. shows, songs, media artists and commercials. As the psychologist Peter Blos describes, "fitting in establishes a pattern of interaction between self and surroundings which slowly shapes individuality and personal uniqueness" (Blos 1979). Peers, who quite typically mirror the popular culture, and the media monopoly have possibly more influence than parents in a child's development of gender (Beal 1984). This is especially pertinent when evaluating this life stage in terms of the child's, "propensity to copy and imitate the actions of others" to facilitate the learning and socialization process which the early adolescent is negotiating (Siann 1994). Yet, as Christenson and De Benedittis indicate in their study on the impact of popular music on young [illegible]e, parents generally remain unconcerned about what their children are listening to on the radio and [illegible] not to be present when children are listening to radio music, leaving kids to process and create meaning from songs either alone or with friends and siblings (Christenson and De Benedittis 1994).

Our research project was designed around the premises that media, in this case popular radio music, is an ever-present and formative part of the lives of individuals and groups in early adolescence and that groups of children of separate genders may extract different messages from radio music as they negotiate, explore and create gender roles for themselves. Our project is an initial step in the exploration of this area which attempts to determine whether a small group of early adolescents are interpreting and viewing popular songs differently by gender.

Our project employed a focus group methodology to six gender-specific groups of fifth grade students from two inner-city grade schools in Seattle, WA. Each group was composed of 6-7 students. Three popular songs (as identified by the researchers and a DJ from a local radio station) were played for each of the groups; these included "Unbreak my Heart" by Toni Braxton, (a slow, melodic ballad), "'Da Dip" by Freak Nasty, (a fast, up-beat dance-song) and "Wannabe" by The Spice Girls (an energetic dance song). The groups, interviewed in school, were asked to listen to the words of the songs and to write down any lyrics that they particularly liked or hadn't noticed before. After each song was played, a written survey was administered which asked if the listener had heard the song before, if they had seen the video, how the song made him/her feel, their favorite line or part of the song, what kind of person would write such a song, and whether the listener could identify with any feeling or activity described in the song.

Each song was discussed in a focus group setting immediately after the short written survey was completed. The group was presented with the same questions to guide group discussion: What was this person singing about? Pick out some lines that illustrate this. Who is the singer speaking to in the song? What do they want that person to do or hear? Do you identify more with the person singing or the person being sung to? If this person were singing to you what would you do? Do you think that this is a happy or a sad song? What are some good things about this song? What are some bad things about this song? What are some of your favorite lines of the song? Although these questions guided discussion and were asked in each group, most groups brought up other themes in the course of discussion and were encouraged to explore them as well.

After each of the songs were discussed in this manner, a final written survey was administered which inquired about demographic information on each of the participants, music preferences and familiarity, and beliefs about the genderization of certain household and professional activities. These surveys indicated that the majority of the participants in our survey reported their ethnicity as African-American. While one-half of the participants are from households in which their mother is the only parent, an additional 29% of participants live with both parents, and the remainder live with grandparents or a single father. Approximately one-third of participants in the study are the only child in their household with an additional one-third from households with two or three children and the remaining third from households with four or five children. The demographic information revealed the the majority of the children live in the area immediately surrounding their schools, both located in an urban, inner-city setting. The questions on the degree to which participants adhered to genderized beliefs of professional and household role participation revealed that the girls in our groups had more stereotypically genderized beliefs about women's roles and activities, while the boys in our groups had more stereotypically genderized beliefs about men's roles and activities.

Several significant themes and differences came up between genders in the discussion and analysis of each of the songs. In the discussion of "Unbreak my Heart" many of the boys were open to more lucid translations of who Toni Braxton may have been singing to; their interpretations included the possibility of her singing to God, angels, her mother, sister, birds or a dog. Although the song's lyrics repeatedly plead, "Unbreak my heart, say that you love me again/Undo this hurt that you caused when you walked out of the door," boys were able to more easily rationalize who she was singing to and why she was singing. As one male child explained, "(She was singing to) her animal (that) could have died or got stolen." Although girls did bring up the possibility of the singer singing to either God or her mom and dad or siblings, they generally adhered to the assumption that Toni Braxton was singing to a lost lover, boyfriend, or husband and did not discuss their interpretations at any length.

Included in the discussion of "Unbreak my Heart," when asked what they would do if this person were singing to them, the girls groups invariably responded that they would return to the person because it seems that he's really sad and feels badly. The boys groups, however, appeared "put off" by the imploring messages of the singer. Those who responded to this question said that they would not return to the singer or that they would "brickwall her", meaning ignore her. One boy responded, "I would go back and then leave. Because, I'd want to speak to her about it and then kiss and stuff and leave her."

The girls tended to draw out more positive interpretations of this love ballad. Primarily, they hailed the singer's ability to express herself in a time of a sadness and went on to discuss the merits of such a strategy in their own life. "(It) makes you feel better to tell someone your problems, then you can go kick it and have fun, go places." One group of boys, however, seemed to have a counter interpretation of women and expressing pain. Collectively, they agreed that

BEST COPY AVAILABLE

women dwell longer in periods of sadness and "can't go on to another." To paraphrase the words of one boy, women are weaker than men because they take a month to get over a painful breakup, whereas men recover in a week.

"'Da Dip by Freak Nasty brought out discussions of a more sexual nature. Lines such as, "slip that money under that skirt," and, "lick you up and lick you down/I ain't finished girl turn around" were repeatedly pointed out by the participants to illustrate the "freaky" nature of the song. This was also a tool in which the girls attempted to differentiate themselves from the women portrayed in the song. When asked who Freak Nasty was addressing, many girls suggested that he was singing to, "the girls and the freaky women that like him putting money up their skirts...strippers." Boys did not make the same distinction. They believed that he was singing to his girlfriend, wife, or to girls in general.

Both boys and girls in every group identified misogynist views in this song. The girls who were opposed to the overt messages of this song stated that in simply listening to the song they felt, "harassed" or "nasty," yet still classified "'Da Dip" as a "happy" song. Despite misgivings about the lyrics of the song, girls made claims such as, "the only thing that we like is mostly the music," perhaps indicating that they were able to enjoy the beat without paying attention to or being bothered by the lyrics. When asked what they would do if someone were singing, "'Da Dip" to them, most girls seemed excited and responded (often emphatically), "I'm not ready for that," claimed one girl, "I'm not doing that." Another responded, "I'm not doing that. I am a free person." Another girl, perhaps continuing the quest to differentiate herself from the women being sung about, stated, "If someone would do that...I would be sad. Because they can't really live a life." However, the theme of sex as a necessary part of the life cycle was identified by one girl in response to another group member who derode sex as "nasty", "I'm happy," she replied, "Because my mom had to do that to have me. And if it wasn't for that I wouldn't be here." Girls in each group identified ways in which the relationships and interactions between males and females in this song were not what they considered acceptable or desirable.

The Spice Girls' song brought forth interesting differences in interpretation between genders. The chorus of "Wannabe" repeatedly declares, "If you wanna be my lover, you gotta get with my friends." This line spurred debate about the meaning of the term, "get with" in groups of boys and girls. Most boys understood the term, as used in this context, to mean, "have social sex" or, "have sex with a lot of people." The boys described this message as a negative one. Girls interpreted the term "get with" to mean, "be friends." With this understanding, they derived a very positive impression of the song. "I would think it was great because then I would get to have more friends," one girl responded. One girl began a sentence in which she was entertaining the idea of "get with" as having sex, but was cut-off by her female peers and abandoned the idea.

There are several themes that arose in the discussions and interpretations of all of the songs. The ability to separate the music video from the interpretation of the actual song was a problem that arose in each group and a limitation of this method of research. Although, as reported in the written survey, girls had seen all three videos at a greater rate than had boys, girls seemed more able to drop discussion of the video and to interpret the song as they'd heard the lyrics. It was a consensus that the video was a more correct interpretation of the song than individual insights. As one boy exemplifies in his attempt to explicate the meaning of "'Da Dip", "It's about girls and boys, it's a kind of dance. I don't know...I haven't seen the video."

The boys in the groups that we interviewed seemed to subscribe to what we later identified as an, "earned" view of relationship, seeing relationship as prize. In "Unbreak my Heart", the boys were more likely to see the failed relationship as somebody's fault, most frequently that of the woman singing. The man had left her, quite simply, because the singer had done something wrong. When asked the question, "What would you do if the singer were singing to you?", one boy indicated that, "she probably did something wrong. She shouldn't have done it." Another responded that he would, "take her money and leave." Although none of the boys could elaborate on what it might have been that the singer had done "wrong", they obviously viewed failed relationships as the fault of one of the partners. The theme of having to be worthy carried over into the discussions about "Wannabe". The boys seemed collectively thoroughly offended with what they interpreted as an ultimatum being set by the singers of the song. They voiced that they lyrics, "If you want to be my lover, you gotta get with my friends" appeared to be a dogmatic order with which they did not care to comply. Comments such as, "You gotta earn his love. What if he don't like 'em (her friends)? He don't have to be friends with everybody!" Responses such as this typified responses by other boys.

To grasp the meaning of the songs, girls typically related the situations presented in the music lyrics to experiences in their own lives. Girls would frequently discuss circumstances in their own lives or the lives of family members in which they had felt or observed a similar emotion to the one being conveyed by the song. When discussing "Unbreak my Heart," and the pain that the singer felt, one girl offered, "Just like when my mom's dad died, she was sad and stuff for a week, 'cause me and my brother talked to her and she felt better." When responding to the question of what "Unbreak my Heart was about, one girl said, "Me and [illegible] cousin had to sing this song for church and it had to do with when you can't hold all the pain [illegible] heart." Another girl, in attempt to explain the "happy" feeling that she had when listening to [illegible]Da Dip," compared it to a time that she'd shared with one of her friends in the group saying, "remember that time we went to the movies, we went to the dollar stores downtown?" When answering the written survey administered after each song, many girls revealed that they had felt similar feeling to those portrayed in "Unbreak my Heart" when they had moved to Seattle or when they had broken up with a boyfriend. One girl shared, "I broke up with a boy that loved my heart...when I had to leave my bomb (attractive) boyfriend that's in Louisiana where I came from."

Another aspect of the adolescent experience for boys is rebuking those [illegible] attempt the exploration of the societal norms of same-sex attractions. As revealed [illegible] discoursing with the boys and in the studies of gender specialist Gerda Siann, "There was considerable stigmatization of children, particularly boys, who cross sex boundaries. Re[illegible]d to this is the phenomena whereby... marginal boys may be [illegible]ased and mocked as bei[illegible]issy' or sometimes in the American setting 'fags' (Siann 1994)." In discussing the song, "'Da Dip," boys repeatedly harbored the notion that the singer was actually wanting to touch boys when he, "put his hand up on your hip." One boy excitedly yelled out, "He did it to a boy! He did it to a boy!" Another boy employed the same interpretation when attempting to answer what he would do if someone where singing this song to him, "I would tell him, man, you better get away from me because I am not dipping with boys." This could also point to this boy's inability to translate the gender of the singer into a female as proscribed by the question, but it also exemplifies the fear of being identified with perceived unacceptable social behaviors, particularly in a group setting. Boys were also careful to monitor the other children who spoke of questionable societal relationships. When a soft-spoken boy raised the idea that the Spice Girls were singing about "social sex", other boys scolded him, "Ewh, your gay!", although his comment did not touch issues of homosexuality, it seemed that they were uncomfortable with his comment and sought, what they viewed as a deviant label for the dissenter. However, the discussion of same-sex relationships of women did not receive the same stigmatization by the boys discussing them. One boy believed that the Spice Girls were directing their song to other women. When asked why he believed this he responded, "Same reason (another boy) thought they were singing to a boy," and discussion continued without any comments from other boys in the group.

Although our study is not definitive due to a small and relatively homogeneous sample size, we do believe that this study identifies several areas that merit further investigation. Our study was developed with the intent to listen to children and to begin to identify whether there is, indeed, evidence for differing perspectives between boys and girls when listening to and discussing popular music. We believe that we have identified an appropriate range of questions and themes to use for larger-scale, future research. The idea of "earned love" that came up in each of the boys' groups would be important to test with different songs than those that we used; perhaps, a ballad by a male artist. Investigating the idea that girls relate more to experiences in their personal lives when interpreting popular music in a group setting would require a larger sampling of children. Although there was an adherence to the interpretation set up by the music video for each of these songs and occasionally confusion in interpretation due to lyrical intelligibility, our research did find that kids actively construct messages from the music that they hear. Due to the amount of time that most early adolescents invest in listening to popular music and the crucial lifestage of gender role formation in which they are located, the area of popular music's influence on and interpretations by early adolescents is an area of crucial study that certainly merits future research.

An Examination of Gift Giving in Post-Modern Society

Megan Kathleen Donovan

Department of Sociology
Union College
807 Union Street
Schenectady, NY 12308

Faculty Advisor:

Prof. Martha Huggins

This study examines the techniques used at the Development Office of a small liberal arts college in upstate New York to make bureaucratic gift soliciting seem personal. Through field research, it has been found that giving at a small liberal arts college is personalized by syncretizing bureaucracy and personalism.

Gift giving, as a face-to-face relationship, helps establish personal relationships and sustain order. In traditional societies, several rules have applied to gift giving: Gifts are given, not solicited; they define social roles; a gift of equal value must be returned to the giver. In industrial and post-industrial America gift giving has taken on an added dimension: Gifts are now solicited.

Researching changes in gift giving, Harry Murray (1990:14) argues that "hospitality is no longer a virtue, it is an industry." In his study of the *Catholic Worker*, Murray found that what had once been personal has become institutional and bureaucratized. Could gift giving now be both personal and bureaucratic? Need it be either one or the other?

Through ten weeks of fieldwork consisting of interviews and observations in the College Relations division of a small liberal arts college, it was discovered that gift soliciting shows syncretism between personalism and bureaucracy. On the one hand, gift soliciting has become routinized--a process that can be taught--in which the people solicited, mainly alumni/ae, are objectified. While, on the other hand, personalism still pervades the gift solicitation process. This duality is successfully maintained by keeping bureaucracy and personalism separate, a process explained by Goffman's (1959) Dramaturgical Theory of life-a-theater, in which interaction spaces are divided between front and back stages. Accordingly, the impersonal bureaucracy of gift soliciting is kept out of the prospective donor's view--in the backstage. An entire vocabulary, analogous to gardening is used in the backstage to describe the gift soliciting process:

> Like farmers, [we see] people [as] the seeds--we plant them, water them (by inviting them to an event), and sometimes we do some major watering (giving them an

948

> honorary degree, or a major recognition). The plant them grows, or it doesn't. This is the part where we try to form a reciprocal relationship, some respond and some don't. With all people it is the same.... to release the gift. [This takes]...cultivation.

The potential donor sees only the frontstage, which is personalized and seemingly unbureaucratic. The objective of gift solicitors is to keep these interaction spaces separate from one another, a process described by college relations solicitors as a "dance." Solicitors interact with potential donors in a way that balances contrived compliments with genuine "sincerity." One solicitor explained that when meeting with people,

> There is lots of complimenting that goes on...--[a person's] achievements, taste, activities--it is like giving them an "A." There is a dance involved in the process, and the dance is one of sincerity to create the trust. You want to compliment, yet gain the trust of the person at the same time. First and foremost is sincerity. I am an ambassador to the institution and I have to be careful when doing the dance.

That some compliments are not sincere points to a moment in which the bureaucratized backstage can be thrust into the frontstage, potentially causing a moment of tension for solicitor and potential donor. At this moment, the solicitor must appear sincere, not letting the potential donor see the planned "script" for this "performance."

The "dance" that balances front and back stages involves using information and ideas generated in the backstage--on how to raise money, on the prospective donor's financial status and interests--to entice donations while still maintaining the image of a personal, charismatic, and sincere frontstage. So that this contrived "dance" is not be recognized by the potential donor, the solicitor must successfully balance front and back stages so as to minimize what Goffman labels "definitional disruptions"--where contradictions expose "an individual who implicitly or explicitly signifies that he has certain social characteristics," in this case sincerity and interest in another, when he does not (Clark and Robboy, 1992:120).

While gift soliciting in the front stage has its personal side, this study reveals that modern gift giving supports Max Weber's (1964) theory of routinization: It has become routinized to the point that solicitors are expected to follow scripted behaviors and demonstrate a scripted charisma to prospective donors. Seeing gift soliciting as an occupation, Weber (in Murphy, 1989:170) might describe the gift solicitor in these terms:

> [the] general evolutionary process...in human society....[has] brought about increasing depersonalization of relations,... growing division of labor, the emergence of the individual as a legal entity, greater specificity of roles, and a loss of solidarity based upon common sentiment.

By combining Goffman's Dramaturgical (1959) and Weber's (1964) routinization theories we can better understand modern gift giving. By keeping routinized gift solicitation in the backstage, personalism can still appear to characterize gift giving even as the process becomes increasingly routinized and impersonal.

LEARNING TO HATE YOURSELF:
HOW HOMOPHOBIA TEACHES GIRLS TO DEVALUE WOMEN

Dr. Harriet Adams

INTRODUCTION

Recent research suggests that with the onset of adolescence many girls begin to exhibit both a loss of confidence in themselves and their abilities, and a highly critical attitude toward their bodies. As a result, these girls dramatically reduce their personal and educational expectations for themselves and other girls. Based on works which chronicle these disturbing results, such as Peggy Orenstein's *Schoolgirls* (1994), Myra and David Sadker's *Failing at Fairness* (1994) and Lyn Mikel Brown's and Carol Gilligan's *Meeting at the Crossroads* (1992), a student colleague, Cinnamon Reiheld, and I developed and implemented a pilot curriculum for girls ages 11-15 at a local summer YMCA Teen Camp at the University of Toledo. Its primary focus was to help the girls learn to reconceptualize their bodies, their personal talents and accomplishments, and their future goals in positive, women-centered terms by providing them with the language and tools necessary to think critically about the position of girls and women in our male-centered society.

Despite extensive reading, however, I was unprepared for and overwhelmed by the homophobia which seemed to taint their relationships with one another, and to perpetuate their negative stereotypes of girls and women. To these girls, the terms "woman" or "woman-centered" were stigmatized as "lesbian," and to make significant the subject of women, their accomplishments, or their legitimacy as role models was labeled "gay." This homophobia became particularly evident in their responses to exercises in which women were presented as role models, or in which we promoted any female-centered group bonding. In addition, many daily incidents in the camp environment, particularly incidents with adolescent boys, served to generate and reinforce the homophobic responses and attitudes present. In this paper, I will present a framework in which to understand the homophobic social climate we observed through the girls' responses - responses I believe help ensure that adolescent girls learn to devalue themselves and ultimately the women they will become.

PROGRAM FORMAT & PARTICIPANT PROFILE

The Teen Camp program was comprised of nine one-week summer sessions. Although some teens attended the camp for more than one week, a total of 390 different teens, 250 girls and 140 boys, attended the camp throughout the summer. Teen Camp participants ranged in age from eleven to sixteen years old, with an average age of twelve. Approximately 1/2 of the teens lived in two parent homes (including step families), 1/4 lived in single parent homes, and 1/8 lived in the foster care system. The remaining teens lived with other relatives. In terms of socio-economic status, the majority of Teen Camp participants came from middle class backgrounds. A smaller number came from upper and lower income level backgrounds. About 1/4 of participants received financial assistance in the form of partial scholarships to pay their Teen Camp fees. Finally, twelve teens with special needs, including autism, physical impairments, and mental disabilities, participated in the Teen Camp program.

Our workshop, *What Little Girls Are Really Made Of*, took place weekly on Mondays and Fridays. Each session lasted approximately two and a half hours, and consisted of a combination of activities from our curriculum. Typically, each group consisted of twenty to thirty girls, which we then split into two smaller groups in order to better facilitate the activities.

ANALYTICAL FRAMEWORK

In the works I read prior to the workshop, homophobia was virtually unmentioned, even when similar exercises were used. For instance, our gender journey exercise, which asked the girls to imagine how their life would be different if they had been "born a boy," was adapted from *SchoolGirls* and *Failing at Fairness*. Neither of these books mentioned similar responses or ways to address homophobia in general. Yet, when we carried out the exercise, the issue of sexual orientation, once introduced, dominated the discussion. The girls scoffed at the notion of "being born a boy" because they would "have to like girls." Because the homophobia was so prevalent, either implicitly or explicitly, in response to other exercises in which women were presented as role models, or in which we promoted any female-centered group bonding, it became increasingly important to discover a framework that would explain the cultural forces that teach women and girls to devalue and stigmatize their relationships with other women, and to fear their collective power in such relationships. The work of Adrienne Rich and Susan Moller Okin not only provided the framework that would allow for such investigation, but highlighted the necessity to include these discussions of homophobia in other feminist scholarship as well. I will present a simplified version of their arguments to be considered as a framework of analysis for the homophobia I observed and its implications for girls and women.

In her article, *Sexual Orientation, Gender, and Families: Dichotomizing Differences*, Susan Moller Okin describes the intricate relationship between the dichotomization of sexual difference and the stigmatization of activities and relationships labeled as homosexual (Okin, 30). According to Okin, the view that men and women are "opposites" forms the rationale for gender inequality in our society (Okin, 37). She further states that because we learn to dichotomize masculine and feminine attributes, and to privilege the former, we learn that men and women's social roles are complementary and that heterosexual relationships are indeed "natural" (Okin, 30, 42). As a control mechanism, then, behavior that deviates from these sex role boundaries is stigmatized as homosexual regardless of a person's actual sexual orientation (Okin, 32). Within this framework, homophobia serves to uphold the gender inequalities present in our society by stigmatizing relationships and activities that are not congruent with traditional sex role norms (Okin, 38).

Adrienne Rich expands this framework in *Compulsory Heterosexuality and Lesbian Existence*. She explains that the inequality inherent in a view of women and men as opposites teaches girls to place men and boys above women and girls, "including themselves, in credibility, status and importance in most situations" (Rich, 645). Likewise, girls learn to view interaction with women and girls as a "lesser form of relating on every level," and to understand heterosexual involvement with men and boys as primary and compulsory (Rich, 645). In this context, homophobia is understood as the stigmatization of any individual action or relationship that serves as a source of power for women and girls to "change the social relations of the sexes, to liberate ourselves and each other" (Rich, 657).

A careful reading of Rich and Okin then reveals a structure through which to understand homophobia and its function in maintaining gender inequality in our society. I believe there are three interrelated components to this structure:

(1) dichotomizing sexual difference,
(2) devaluing relationships with women and girls, and
(3) perpetuating gender inequity through homophobia.

I will use this structure to analyze the girls' responses to specific exercises in order to demonstrate how homophobia maintained gender inequality within the camp, and the implications of this inequality for the girls and the women they will become.

DICHOTOMIZING SEXUAL DIFFERENCE

The first, and perhaps most crucial element in the structure of this 'homophobic feedback loop' is the dichotomization of sexual difference. Two exercises in particular demonstrated the extent to which the girls had learned both to dichotomize masculinity and femininity and to privilege the former in our society: "Word Wheels" and the "Gender Journey" (Okin, 39).

Adapted from the *Action Guide for Girls' Education*, "Word Wheels" was an exercise in which we asked the girls to make a list of personality attributes associated with the words "girl" and "boy" (Bay Area Network, 8-11). Through their responses, the girls described a social world in which boys and girls, women and men, were viewed as virtual opposites. Although there were notable exceptions, girls were generally described as sweet, sensitive, loving, nice, and understanding while boys were described as mean, intelligent, weird, tough, messy, and above of all "perverted." A few girls even supplemented their lists with statistics: "99% of boys are perverted, 1% of girls are." To the girls, "perverted" was code for "sexual,"

BEST COPY AVAILABLE

meaning boys had the right both to have sexual feelings and to act on them; girls do not have such rights. The significance of this comment lies at the heart of our rape culture mentality: women and girls are to act as the moral force in relationships between women and men, they must stop men from acting on their natural, "perverted" impulses, and they are in control of the level of sexual expression in any relationship. When they fail to maintain that control they choose to subject themselves to the "perverted" male, and deserve the consequences. From this exercise, it is clear by age twelve that these girls know and understand the warped logic by which we define women's and men's sexuality. Even more disturbing was that the girls described all these characteristics as "naturally" being associated with one sex or the other, not social constructed, and not subject to change (Okin, 36).

In a corollary to this exercise, the girls were also asked to make a list of the occupations women and men hold. It was apparent from their responses that the girls had learned to believe that their different, if not opposite, personality characteristics equip girls and boys for different jobs when they become women and men. Although two of approximately twenty girls believed that women and men could hold "the same jobs," the majority of girls listed occupations consistent with their stereotyped view of women and men as opposites. Women were described as nurses, "cleaning ladies", waitresses, secretaries, models, teachers, baby-sitters, moms, and actresses while men were described as construction workers, mechanics, executives, doctors, custodians, plumbers, principals, presidents, "bug killers", professional athletes, firemen, garbage men, and police officers. The obvious economic, power, and status differentials between these male and female occupations is one of several indicators of the implicit knowledge girls have of gender inequity in our society, and the consequences of that inequality for girls and women.

The "gender journey," which asked the girls to imagine how different their lives would have been if they had been born as boys, demonstrated the extent to which the girls' view of boys and girls as opposites caused them to value boys' lives over their own. Their responses, which fell into four categories, clearly reflected a sense of advantage in terms of personal freedom, access, and leisure for boys, and disadvantage for girls. The first category of response testified to the tyranny of appearance in the lives of adolescent girls:

> "We could sleep in because we wouldn't have to spend so much time getting ready."
> "We wouldn't have to worry about whether our clothes matched perfectly or not."

The girls were clearly jealous of the "free time" boys enjoyed as a result of not having to tend to their appearance in this manner. An important question to ask is what boys do with this free time, what does it means that the girls are slave to a time and energy consuming physical perfectionism that boys are not. Another category of response revealed the extent to which girls consider themselves biologically vulnerable in our society:

> "We wouldn't have periods, or have to worry about getting pregnant."
> "We wouldn't have to worry about our weight as much."

Issues of weight management were extremely important to these girls as over half of them testified to being on a diet at least once, and not one girl was over the age of fourteen. A third category demonstrated the greater physical, behavioral, and attitudinal freedom boys enjoy over girls, and the value girls place on that freedom:

> "We could be more aggressive."
> "We would have to play war and G.I. Joe."
> "We wouldn't have to do as many chores around the house."
> "We could always play ball; we wouldn't have to prove that we were good enough."

The final comment, once introduced, completely dominated the discussion:

> "If we were boys, we would have to like girls!"

This possibility of "liking girls" was met with total horror by the other girls, and was followed by a stream of homophobic comments. These comments might well have been dismissed as social immaturity, however, they quickly became comments condemning even homosocial activities between girls. The magnitude of force behind these comments indicated that if "women liking women," even in intense friendship, was so forbidden, then "women hating women" must be the norm. At an age when they are encouraged to abandon their relationships with girls and women in favor of relationships with boys and men, these girls have learned that the more they stigmatize female-centered relationships, the easier it is to abandon them. In light of the structure provided by Rich and Okin, I believe this incident was illustrative of how a dichotomization of the sexes in which the male is privileged led the girls to view interaction with one another as lesser, almost deviant, and to privilege their relationships with men instead (Okin, 30; Rich, 646).

DEVALUING WOMEN & GIRLS

The extent to which the girls devalued positive interaction with women and girls, the second element of the structure for understanding homophobia, was demonstrated by two specific exercises, the "Women in American History Lesson" and "Your Everywoman," an exercise in which the girls were asked to identify a woman they admire and why. The goal of these exercises, to help the girls identify positive female interaction in their lives, came into direct conflict with their view of relationships with woman as lesser, deviant, gay. The girls were clearly very uncomfortable with focusing on women as positive role models in these activities. Over and over, the girls stressed verbally that they "look up to men," and that they "don't like thinking about women or hanging out with them much." They explained that they were "at an age when they should be thinking about boys," and that they were upset by this exercise for two reasons: "we don't like being separated from the boys" and "it's gay" to think about women. These overtly homophobic feelings indicate that not only have these girls learned to stigmatize relationships with women as valued companions and role models, they are highly sensitized to and terrified of situations which even promote such relationships (Rich, 657). According to Rich, the consequences of this homophobia have been severe: it has meant the loss of relationships that provide the power for women and girls "to change the social relations of the sexes, to liberate (themselves) and each other" (Rich, 657).

MAINTAINING GENDER INEQUITY THROUGH HOMOPHOBIA

An exercise about appropriate sex role boundaries revealed the entire structure of how homophobia maintains gender inequity in our society, including the severity with which transgressions against the structure are punished. In an adaptation of Matina Horner's 1969 study, we split the girls into several groups and asked them to devise a skit around a particular situation. The situation followed as such:

> After report cards are handed out in class, Molly (Brian) finds out that she (he) has gotten straight A's again, for the third grading period in a row. Describe what follows in the classroom.

One group of girls acted out the situation involving Brian, another group involving Molly. When Brian received straight A's, there were no negative consequences for Brian in the classroom. He merely exchanged a "high five" with his friend Ryan, who also received straight A's. The group of four girls who received the situation involving Molly, however, devised the following skit:

> Molly walks up to her three best friends, tough girls who are smoking. Overjoyed, she tells them that she just got all A's again. The girls pull Molly by the arm, tie her to a tree, pour gasoline on her, and light her on fire with their cigarettes.

This horrific characterization of the consequences of female success conveyed two important messages. Foremost, acting outside of the appropriate sex role boundaries, girls and women as successful for example, was a punishable offense for these girls. Also, attempting to celebrate that success with other girls required those girls to respond with hostility and force. Using Rich and Okin, we are able to understand this incident as a homophobic reaction designed to teach women and girls to devalue and stigmatize their relationships with other women, and to fear their collective power in such relationships, thus nearly eliminating the possibility that women will work collectively to end gender inequity in our society.

CONCLUSIONS

The implications of uncovering this structure for understanding how homophobia maintains gender inequality can be observed in the way it manifested itself in the teen camp environment. Three specific types incidents occurred on a daily basis in the camp environment which generated and reinforced one or all of the elements necessary to maintaining a homophobic climate: lack of camp programming for boys, name calling and sexual harassment.

Because our program worked exclusively with the girls, the Teen Camp staff agreed to provide alternate programming, character development exercises, for the boys during this time period. However, we soon discovered that this programming not only did not exist, but was replaced with activities, such as sports activities or free time, that worked directly against the stated goals of our workshop. The boys frequently played in the field adjacent to our workshop, and as a result distracted the girls from our exercises. The girls questioned why the boys were getting "free time," choosing their activities, "being loud and playing" while they had to "sit still, listen, pay attention, and behave?" One day in particular we addressed this problem by playing an all-girls kickball game, and having a great time. However, it was incredibly difficult within this environment to challenge the girls' negative stereotypes of women and relationships with women when the camp programming and management served to reinforce those very stereotypes.

In the camp, the words "girl," "girly girl," or "feminist" were the most derogatory insults that could be used against both girls and boys alike. According to the girls' explicit definition, a "girly girl" is a "girl who acts too much like a girl, wears dresses too much, is afraid of spiders, and doesn't like sports enough." Obviously, an overindulgence in what is considered "girl" is bad. That the girls insulted each other in the same manner the boys insulted one another with the word "girl," indicates that the girls have an implicit knowledge of the lack of power inherent in stereotyped feminine behavior and attributes.

If use of the word "girl"indicated a lack of female power, then the use of the word "feminist" as an insult indicated the contempt and negative stereotyping with which female power was confronted in the camp environment. During free time, a group of boys and girls were gathered around a table making popular necklaces and bracelets out of beads and string, when one boy began discussing his dislike for a particular girl at school. Loudly, he exclaimed "she is a feminist, because she doesn't shave her legs," to which I responded "I am a feminist." The boy looks at my legs, notices them shaved, and doesn't speak for almost five minutes. An amusing but telling story of the manner in which feminism, and by extension relationships and activities that foster a sense of power for women, was confronted and devalued in the camp environment.

Even more prevalent than the name calling were the daily incidents of sexual harassment. These incidents included a game called "Nervous" which each new girl had to play on the bus in order to be initiated by the boys into Teen Camp. The game began when a boy, usually a very popular boy, placed his hand on a girl's ankle, and moved up her legs, down her arms, and toward her breasts and genital area. Throughout this humiliating touching, the boy continually asked, "Are you nervous yet?" The point at which the girl answered "yes" determined her status as a prude, cool girl, or slut. Although the girls outnumbered the boys nearly two to one every week, they did not have a sense of collective efficacy to stop the sexual harassment. Standing up for yourself or another girl meant alienating yourself and running the risk of being labeled "gay." Also, the camp counsellors were less than supportive of the girls who had exposed sexual harassment in the camp. They defended the boys and accused the girls of seeking retaliation against boys who would not date them. Under these circumstances these girls learned to fear their collective power in relationships with other girls to end sexual harassment - the ultimate use of homophobia ensure the maintenance of gender inequality in our society.

An understanding of the structure through which homophobia maintains gender inequity in our society does more than illustrate the problems girls and women face; it also provides hope and direction for substantive change. If we as a society no longer viewed women and men as opposites, we could judge the appropriateness of aggressive or assertive behavior, for instance, "in accordance with the circumstances, not the sex" of the individual (Okin, 32). As a result, women and men who demonstrated interests, talents, and personal styles that are not consistent with stereotypical sex role norms then would not be stigmatized as homosexual (Okin, 32). And most importantly, women and girls would no longer have to devalue and stigmatize their relationships with other women, giving them access to a source of knowledge and power they have never known.

Dr. Nadia Rubaii-Barrett

In 1992, the "Year of the Woman," women doubled their representation in the United State Congress. Yet, to what extent did this increase in representation result in greater attention to "women's issues?" For the purposes of this paper, "women's issues" are defined as those which have been the focal point for the various stages of the Women's Rights Movement. This historical movement includes the Suffrage Movement, the Civil Rights Movement, and the issues which highlighted the "Year of the Woman" in 1992. This paper examines the "Year of the Woman" in the context of this historical movement and assesses the extent to which the electoral gains in 1992 resulted in concrete actions to befit the label. The analysis shows that women in the 103rd United States Senate did not sponsor a significant among of legislation on women's issues. Yet, the research helps clarify the effect of the 1992 elections on the United States Senate and enhances the understanding of women's issues in the context of current public policy dilemmas.

BACKGROUND

In almost every culture, roles are defined for individuals based in a large part on gender. In turn, these gender roles contribute to different experiences and different priorities for women and men. To define women's issues, this paper examines what issues were predominate in the Women's Rights Movement from its earliest stages through the "Year of the Woman" in 1992. The three major stages in the Women's Rights Movement include the Suffrage Movement, the Civil Rights Movement, and the "Year of the Woman."

The Suffrage Movement began in 1849 with the Seneca Falls Convention and continued through the New Deal reforms in the 1930's. The Seneca Falls Convention allowed women to call for equality and to document women's issues in their Declaration of Sentiments and Resolutions (Chafe 1991, Dubois 1978, Gurko 1974). These issues included equality in their professions, in marriage, and in legal rights (Porter 1918). Since these issues paralleled racial minority issues, the Abolitionist Movement and the Suffrage Movement worked together for equality in the Constitution. Yet, when the Thirteenth, Fourteenth, and Fifteenth Amendments were ratified to the Constitution, they supported race not gender (Crocco 1995). This sparked the movement's call for women's right to vote to be included in the Constitution. This issue resulted in the ratification of the Nineteenth Amendment in 1920. Thus, women addressed the right to vote issue and it resulted in policy.

Women continued the Suffrage Movement to address more women's issues related to greater society concerns such as social reforms and fair labor standards in the New Deal. The country as a whole was addressing the greater society concerns because of the Great Depression, but women augmented these reforms because of their promotion of individual and family well-being as women's issues (Ware 1981). President Franklin Roosevelt recognized women's increased political participation when he appointed Frances

Perkins as the Secretary of Labor. Under the Department of Labor, she included women in the construction of legislation addressing women's greater society issues such as the Social Security Act of 1935 and the Fair Labor Standards Act of 1938. Thus, women's issues were reflected in the New Deal reform policies headed by Frances Perkins. As seen in the previous examples, women's issues in the Suffrage Movement became policy because of women's motivation and organization. Women continued this trend in the Civil Rights Movement.

Women again joined forces with racial minorities in the Civil Rights Movement in their quest for equal rights in 1960-1970. The Civil Rights Movement addressed the issues of racial and gender discrimination. The movement's discrimination issue resulted in policy when The Civil Rights Act of 1964 passed. Although this act included women's issues, women reintroduced the Equal Rights Amendment which exclusively addressed women's issues. This amendment did not pass, but women continued to address women's issues which helped to establish the "Year of the Woman" in 1992.

The "Year of the Woman" label stemmed from the political arena centered around women's issues (Crispell 1992, O'Reilly 1992, Roberts and Cohen 1992). These issues included Anita Hill's allegations of sexual harassment during the Clarence Thomas conformation hearings, and abortion because of the recent Supreme Court abortion decisions.

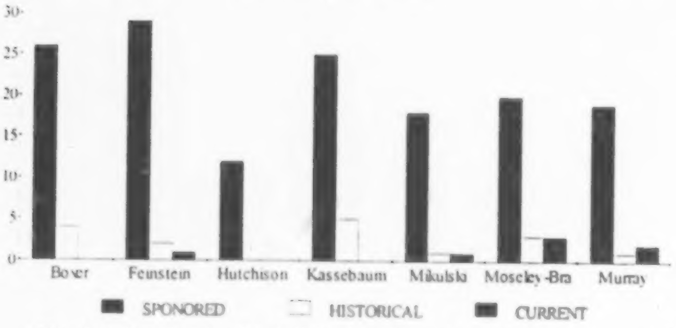
Women's rights groups and candidates campaigning for the 1992 election recalled the Clarence Thomas conformation hearings to emphasize the issue of sexual harassment. This was evident in *Newsweek*'s public opinion polls that in 1991 showed only twenty-seven percent of women believed Thomas had harassed Hill compared to fifty-one percent in 1992 (Salholz 1992). As seen in this poll, the issue of sexual harassment addressed in the Thomas conformation hearings was highlighted by many women's groups and women candidates in the 1992 election.

The abortion issue had its primary impact in the Supreme Court system as seen in *Roe v. Wade* (1973). Since this landmark decision, the Court has defined abortion through many cases in the 1980's and the early 1990's. The developments in the early 1990's cases caused abortion to become a primary issue in the 1992 election. This was evident in the women's groups that formed and grew with the abortion litmus test. Starting in 1991, Women in the Senate and the House (WISH) supported pro-choice women in either party. By March of 1992, it had raised $180,000 and enlisted 250 members (McDowell 1992). Also, Early Money Is Like Yeast (EMILY's List) reached its annual fundraising intake in the first few months of 1992. The political emphasis placed on sexual harassment and abortion by women's groups and women candidates resulted in women doubling their representation in Congress (Githens, Norris, and Lovenduski 1994). Because of the increased representation, this paper analyzes legislation introduced in the 103rd United States Senate by the women elected in 1992 to see if it policy changed concerning women's issues.

ANALYSIS

Given that the primary issues in the historical Women's Rights Movement were addressed in associated legislative policies, this paper assumed that the issues raised in the "Year of the Woman" would result in relative legislative policies. Using the issues defined in the Women's Rights Movement as definitions of women's issues, this paper conducted a content analysis of the bills sponsored by the women in the 103rd United States Senate to determine if the issues addressed in the "Year of the Woman" became policy.

To better analyze this assumption in the chart below, the first column indicates the total number of bills sponsored by each woman. The second column denotes historical women's issues such as greater society concerns noted in the Suffrage Movement. The third column records the current women's issues addressed in the "Year of the Woman" including sexual harassment and abortion.



BILLS SPONSORED

The chart illustrates that the analysis of the vast majority of the bills sponsored by women in the 103rd United States Senate did not address current women's issues. While the Women's Rights Movement has contributed to defining key issues in each of its major stages, the issues which lead to the unprecedented electoral gains in 1992 did not directly or immediately translate into new public policies. This is evident in the content analysis of the sponsored bills below.

Barbara Boxer's bills concerned environmental issues, tax issues, and women's historical issues. Environmentally, Boxer's bills gave federal protection to certain lands and species. Her bills concerning taxes designated tax breaks for certain tax categories. Finally, she did address women's historical issues in crime prevention and health care related bills. In S 470 she sought to amend Chapter 41 of Title 18, United States Code, to punish stalking. In S 765 she wanted to amend the law to provide women employees the opportunity to be notified of material coverage restrictions and remedies for violations of benefits under group health plans. In S 1454 she addressed the issue of breast cancer research. Lastly, in S 1506 she wanted to provide training for the health profession's students on the identification and referral of domestic violence victims.

Dianne Feinstein's bills centered around Defense Base Closures and Realignment Act of 1990. Feinstein wanted to amend the Defense Base Closures and Realignment Act of 1990 to reduce its impact on her state. She addressed historical women's issues in the law and child support. In S 2162 she wanted to provide for protection from sexual predators. This protection was for everyone, but it affected women because of the rape issue. In S 2528 she was concerned with improving and strengthening the child support collection system. This affects women because they are the ones who usually collect child support for their children. She addressed current women's issues in S 1864 by trying to prevent sexual harassment in the work place.

Kay Bailey Hutchison's bills centered around economic issues. This included tax cuts and incentives for businesses. She did not sponsor any bills in regards to historical or current women's issues.

Nancy Landon Kassebaum's bills concerned a variety of areas such as economics and issues in her state. She sponsored five bills that included historical women's issues. In S 325 the goal was to reform health care for easier access. In S 1746 the issue was establishing a youth development grant program. In S 2010 the incentive was to allow easier access to effective drug treatments for children. In S 1950 the plan was to update OSHA regulations. Last, in S 1891 the objective was welfare reform.

Barbara A. Mikulski sponsored bills that concerned an assortment of issues including federal employee benefits. She addressed historical women's issues in S 1310 by extending grants in the Public Health Service Act to breast and cervical cancer. She addressed current women's issues in S 1463 by amending the Elementary and Secondary Education Act of 1965 to address gender equity in math and science.

Carol Moseley-Braun sponsored bills concerned mostly her state's interest as a whole. She addressed historical women's issues in S 922, S 1460, and S 2034. In S 922 the goal was to modify child support court orders between states. In S 1460 the issue was to amend the Elementary and Secondary Education Act to include child abuse protection. In S 2034 the objective was to improve libraries. She addressed current women's issues in S 1466, S 1468, and SJR 188. The intent in S 1466 was to improve gender equality in secondary education. The objective in S 1468 was to improve gender equality in higher education by amending the Higher Education Act of 1965. SJR 188 designated 1995 as the year of the Girl Child.

Patty Murray sponsored bills that centered around a variety of issues including the fishing industry. She addressed historical women's issues in S 2505 by trying to improve Washington State health care through state preemption of national health care. She addressed current women's issues in S 1037 and S 1079. S 1037 wanted to amend the Civil Rights Act of 1991 with respect to its application. S 1079 tried to require that employers post information for their employees concerning sexual harassment under Title XII of the Civil Rights Act of 1964 (Congressional Record 1993, 1994).

This content analysis clearly shows that women's issues, either historical or current, were not the primary concern for the women elected to serve in the 103rd United States Senate. Thus, this paper considers the reasons for the discrepancy between the expected results and the actual results.

CONCLUSIONS

This paper assumed that since women significantly increased their representation in Congress, issues from the 1992 election would be the primary focus for the women elected to the Senate. Yet, the analysis of the bills sponsored by the elected women did not agree with this assumption. Instead, the bills centered around a variety of issues from military base closures to the fishing industry, most of which had very little to do with the issues which define the Women's Rights Movement.

Three reasons for the disagreement between the hypothesis and the results of the content analysis include: (1) women's representation did not increase enough to warrant isolated emphasis of women's issues, (2) the elected women have to represent their constituents' interests before their own, and (3) the limitations of the research methodology in this thesis.

One possible reason for the disparity between the expected results and the actual results is that although women's representation doubled, it was still not enough of a significant gain to warrant women's issues receiving isolated emphasis (Darcy, Welch, and Clark 1995). While women made substantial gains in 1992, they still only held seven of the one-hundred seats in the United States Senate. Thus women should continue to increase their representation so they can emphasize their issues. They can accomplish this by organizing at the grass-roots level to elect more women to Congress and/or to make their concerns heard.

Another reason is the fact that these women had to represent their constituents before their own interests. If these women were elected from states that were all women, they could just represent women's issues. But obviously, all states are comprised of women and men. Thus, the issues they addressed centered around issues that concerned both women and men in their particular state. This is the ideal way for the United States electoral system to work, thus the limited attention women's issues received is understandable.

The methodology applied in this thesis had several shortcomings. This thesis only examined bills sponsored by women in the 103rd United States Senate. A more extensive analysis would include the activities of women in the House of Representatives, would examine bills sponsored over several years following the election, and would analyze voting records as well as sponsorship patterns. Future research using more sophisticated and comprehensive methods might reveal a relationship between the 1992 electoral gains and the advancement of women's issues through public policy.

Fortunately, there are many ways to measure the impact of women's issues in society. Women's issues have increased in importance since the Seneca Falls Convention in 1849; thus, women have gained in their quest to address their issues and more clearly define their roles in society This thesis recommends that women continue their political participation to attain their full potential Congress and other institutions

Popularity The Crisis and Culture of Adolescent Girls

Cinnamon Reiheld
Women's Studies

Faculty Advisor Harriet Adams

A girl's coming of age in Western culture is defined as a crisis contextualized by popularity which effects an individual's perception of who she is and what she can accomplish The popularity crisis creates a culture of competitiveness where it is "every girl for herself" In Making Connections (1990) Carol Gilligan writes that "the central problem—feeling abandoned by others—[is] a problem of disconnection, and often [leads] to desperate actions at connection" (Gilligan, 9) As a summer intern, I witnessed the process of girls battling with the issues surrounding the culture of "every girl for herself" These girls *needed* to be popular at all costs This need manifested itself through hurting each other verbally and emotionally The paper theorizes in terms of Gilligan's paradigm "connection"

During the summer of 1996, I worked with adolescent girls in workshop I developed with a student colleague, entitled "What Little Girls are Really Made Of" The goal of the workshop, which we implemented in a YMCA day camp, was to heighten girls' awareness of their capabilities through self-realization and gender awareness The co-educational camp was for 11-16 year-olds and the girls' ages ranged from 11 to 15 years The workshop, which was conducted for three-four hours a day, twice a week, ran from July 8, 1996 to August 16, 1996 The number in attendance for the workshop varied from fifteen to twenty-five girls The girls differed in socio-economic status, ethnic groups and familial structures From the time we walked in, it had already been determined who was popular and who was not Unfortunately, we didn't see it so clearly on the first day It took a while before we identified the division between the girls as one of status--the elite and those longing to be the elite The girls had labeled the division as "Popularity"

The basis of this intervention was research done by Carol Gilligan at The Willard School for Girls, documented in the book Making Connections (1990) Our intent was to explore Gilligan's theory of connectedness, which examines the conflict in adolescent girls between their connection with themselves and their connection with others In analyzing the girls' responses to exercises I will later describe, I began to realize that the issue of popularity was so central and so large that it requires its own individual theory Gilligan defines a girl's coming of age in Western culture as a crisis In studying her work and through the workshop, I found that an integral piece of the phenomenon she was uncovering is what I theorize as the crisis of popularity

Popularity is the state of being accepted into the highest group of peers, the elite Popularity is an on-going competition for a very small space into which others are constantly trying to crowd The more "popular" people there are, the less popularity is valued If everyone can be popular, then popularity has no value By definition, popularity depends on others' exclusion, while striving to maintain personal inclusion Thus, both achieving and maintaining popularity is time-consuming, costly, and essentially traumatic The crisis of popularity is the detrimental compromise of one's and others' feelings, thoughts, and ideas for the sake of acceptance of a group This crisis damages a girl's sense of self-worth, at the same time that it appears to be essential to this worth, which in turn affects her perception of who she is and what she can accomplish Popularity can justifiably be termed a crisis because of several factors, beginning with the observation that popularity defines the underlying structure of girls' relationships It requires continual preoccupation, it is engulfing and it produces ongoing stress Every day girls walk, talk, and hold their head according to their popularity The way they interact with each other and the way they present themselves revolves around their acceptance, or lack of, or aspiration towards, a particular group They feel a compelling need to behave a certain way to either maintain their status or to hide their non-popular status These behaviors are not usually read as signifiers of popularity Yet in examining these signifiers and the girls, they become a key point in understanding the crisis of popularity In fact, they were recognizable to us from our own remembered experiences in adolescent peer groups This popularity problem was revealed as we watched not only a division between the girls but also mistreatment of some by others, which was having a greatly negative effect on the girls being mistreated This was the crisis going on within teen camp and the girls' lives Because this issue of popularity appeared to my colleague and me to be so central, we developed an exercise to further explore this issue of status. I am going to begin by describing that exercise and what it revealed. I will then analyze the girls' responses to that and three other exercises in terms of what they uncover about the central trauma of popularity.

The girls were given an unfinished statement, "In order to be considered popular a girl has to....", and asked to write down how they would finish the statement. Michelle, one of the elite, wrote that in order to be popular, a girl has to "have cool clothes, be pretty, and be stuck up." Other responses included:

-You have to have cool hair
-You have to talk with an attitude and act like you are "all that"
-You have to be prep or a slut
-You has to be stuck up
-Depending on your school you have to either be smart or act stupid

As a side note, I would like to address the affect of popularity on academics. As you can see from the last statement, popularity does effect a girl's performance in the classroom. The girls also wrote in this exercise that getting good grades is low on the priority list when being or attempting to be "cool". These two comments together are related directly to popularity with boys. The girls held firmly the idea that men don't like smart women or female competition. Girls striving for acceptance are willing to compromise their academic success, which as we know, correlates with collegiate success and choices and, in turn, career choices and success. Girls are not realizing their potential to do amazing things because of their struggle for acceptance. This reiterates my point that popularity can be defined as a crisis.

The types implicit in this list will be later discussed. In the discussion after the exercise, Michelle added that one must be "mean" to the unpopular people and act like a "slut." In the same breath, she claimed her popularity was gained by being good at sports. When confronted with the obvious inconsistency between her written answer and her personal method of attaining the same goal, she claimed that although what she had written was true, she had beaten amazing odds to join the ranks without filling any of the criteria she listed. Michelle then admitted that she had acquired status by being mean to people that were not as "cool" as she. Lisa, a popular girl, wrote that you have to "respect yourself and others, but sometimes you have to make fun of people." No one could answer my question of who decided who was going to be made fun of and who was going to be respected. In comparison, Vikki, a non-popular girl, wrote that you have to be stupid, or have no common sense, you have to have lots of money or be liked by those that do. Other non-popular girls wrote that you have to be mean, act like you are "all that", and act, dress, and do your hair "cool". One girl wrote you have to wear clothes from the Gap. Lindsay, a popular girl, added to our discussion that you have to "have a good personality and be well taken care of", which they translated as meaning you have to be clean, have nice clean clothes, and do your hair and make-up. The importance of image was very prominent in these definitions.

These contradictory statements accompanied the comments above:

-Be yourself
-Try not to act like someone else
-Respect yourself and others
-Realize that people who only like you for your looks are not your real friends

Reprinting these later in the weekly magazine created using the girls' work, as an alternative to the popular teen magazines, my partner and I wrote an article commenting on how the second list contradicted the first list. We asked the girls how they were to "be themselves" if they were all wearing uniforms from the Gap. In the discussion following the exercise, many girls described a system of "types" a person can be. They named the following categories:

- prep: well dressed, well made up and taken care of. The most desired of all categories for majority of girls. Can be a combination of this and another acceptable type.
- girly-girl: behaving too much like a girl
- slut: behaves in extreme sexual ways. Exploits herself for boys.
- tomboy: likes boys' things; like sports and worms. This behavior is expected to be outgrown by high school. After that point, it becomes unacceptable, uncool

- skank: unclean, not well taken care of, troublemakers. Lower class
- goody-goody: excels academically, tattletale, teacher's pet
- nerd: similar to a goody-goody, but lacks the air of a goody-goody, more self-conscious
- bitch: unable to get along with others. Boyfriend stealer. A general term that can be used in any situation
- wannabe: a determined outcast although tries to imitate the popular.

Of these types, only three—the prep, slut, and tomboy—were considered popular. The tomboy turned non-popular at a certain time in a girl's growth and the slut required the girl to either sexually exploit herself for boys or others must believe she has sexually exploited herself for boys. All the girls knew of and understood these labels. Outlining acceptable behavior and labeling girls in such ways evolved the crisis of popularity.

These defined categories framed the meaning of an exercise in which each girl was paired up with another she would not normally talk to or interact with--in essence, a popular girl was paired with a non-popular one. We had wanted the girls to have a chance to get to know someone they would not simply because they were not of the same status. We thought having them in pairs would lessen the influence being in a large group would have and they might open up to each other more. They were to separate into these pairs and talk for ten minutes. At the end of the ten minutes, they were to come back together and each was to "become" the other girl by introducing herself as the other to the rest of the group. Attempting this exercise removed all doubt, if there was any, that popularity status was of the utmost importance in the girls' social structure. The idea of being paired up with an unpopular girl revolted the popular girls. They screamed, argued, pouted and blatantly refused to talk to someone "out of their league." In turn, when some of the popular girls acted this way, the non-popular girls reacted in the similar ways. The non-popular girls I watched lowered their heads knowing that their partners felt this way about being paired up with them. They then become more aggressive as a group and physically moved together and expressed same idea that the popular girls had—they did not want to be paired up with them, either. Their reasoning, however, was different. They did not want to appear to be the pathetic end of the stick. Thus, they acted revolted at the idea also, but in fact, they wanted the opportunity to become friends with the "cool" girls in hopes that they would join the "cool" rank. If nothing else, they just wanted to be friendly with the girls so they would stop being so mean to them.

An example of the behavior of the popular girls can be shown through the actions of Mirra, a popular eleven-year-old, who was astoundingly cruel to the girl we had paired her up with. Mirra refused to go with her partner and begged to switch partners. Her behavior allowed the other girls to stand around waiting to see if I would give in to her plea. Mirra called her partner "stupid" and "ugly" in front of her, and whispered and laughed at her with the other popular girls. Katie, the inflicted partner, sat quietly with her head hung in embarrassment. A quick refusal on my part forced Mirra and the others to break into the pairs that we had put them into. After a period of forced dialogue, the group gathered and introduced their partners. When it came time for Mirra to introduce herself as Katie, she told how many brothers and sisters she had, where she went to school, and what grade she was in. Mirra had not learned anything about Katie, especially how she had made Katie feel. My colleague asked Mirra, "Katie--how did Mirra make you feel when she didn't want to work with you?" Mirra answered that she was not really Katie so she could not answer a question like that. Mirra then told Katie in the form of a question that if Mirra had hurt her feelings Katie would have told her--"right?" Having already been humiliated, Katie was not about to admit that Mirra had hurt her feelings; that would be subjecting herself to even more humiliation through vulnerability. By admitting her feelings had been hurt, she would be allowing Mirra to inflict more embarrassment. Letting Mirra know that she could make Katie feel bad was, in Katie's mind, social suicide.

This episode reinforced Michelle's earlier claim that a criterion of popularity was the ability to be mean to those "beneath you". It would be easy to say that these girls simply did not have a conscience, that they had no regard to each other's feelings and they were simply innately cold-hearted, but it went deeper than that. One girl that made this apparent was Lindsay, on whose face you could see a tinge of guilt for being exclusionary and mean to others. The discussion following the exercise was led by Lindsay. Lindsay was popular and stated that she did not enjoy being mean to others, but her fear of losing her status and being treated like "those other girls" was too great to stop her behavior. It was apparent that Lindsay was developing conflicted feelings as she tried to sort out her behavior Forcing Lindsay, through questioning her explanation, to verbalize her actions made her see how destructive her behavior was to the other girls' feelings. As for the other girls, they were informed by Lacey, the youngest girl in the group, that the goal of the exercise was to learn the importance of giving all girls a chance, because not doing so was not fair to either girl. She concluded that not doing so would result in someone getting treated badly for no reason and someone else missing out on a good friend. I do not believe I could have said it better than this insightful eleven-year-old.

Referring back to the "types" the girls, I pointed out that not are they only are a limited number of categories, but only three of the total were acceptable. The next exercise reveals and reinforces my concept that a limited acceptable "typing" system can effect a girl's sense of self and what she can accomplish. An exercise that illustrated this was titled "Draw a Scientist," from the Action Guide for Girls' Education developed by the San Francisco Bay Area Network for Girls. The task was to draw a scientist. The girls from the workshop repeatedly drew men, and not only men, but men with crazy hair standing on end with exploding chemicals or fires. All the girls drew unattractive people, most males, and all being stereotypical depictions of the mad scientist. This image was completely at odds with the image a girl must maintain to be popular. The popular stereotype of a "scientist" not only excluded women, but made the field of science seem "uncool" and "unfeminine." Mirra, after noticing her neighbor draw of one of the few women, said outright, "Girls can't be scientists!". Holly drew a female scientist working in the Pond's Institute of Technology. This was a welcome departure, yet implied that particular girl thought women could only be scientists in a pink-collar environment, like a cosmetics company. In this crisis of popularity, one cannot expect a girl who thrives off acceptance to pursue a field that is unaccepted by her peers. Breaking out of the acceptable roles, the types the girls identified, jeopardizes a girl's chance to attain this most wanted prize of being popular.

The next exercise was designed to demonstrate to the girls how it felt to be in different roles, roles like the ones they put on each other, unsubstantiated, with no basis. The girls were split into two groups and each group was to create a product and decide how to sell it. Unknown to them, our specific aim, based on their own description of popularity, was to reverse the treatment each received as a popular or non-popular girl. Taped to the forehead of each girl was a note card she had not seen, with instructions telling the others how to treat her. An example of the instructions on the cards were as follows:

-Treat me like I don't know what I'm talking about
-Treat me like I think I'm all that
-Ask me what I think
-Tell me what great ideas I have
-Laugh at everything I say

This array of treatments reflected what girls said they faced every day in school and in their peer groups. It was decided beforehand by my colleague and me that we would give them cards that either illustrated how they themselves usually treated other people or exposed them to better treatment than they usually received, depending on their popularity status. The announced goal, to create a product, necessitated abundant interaction. The non-popular girls enjoyed the exercise, where as the popular girls did not. In one group, several incidents occurred that can be linked to popularity. Lindsay, one of the popular girls, had the card "laugh at everything I say." She was visibly frustrated but kept saying aloud that she didn't care and what we were doing was stupid. Mirra and Erika, two popular girls, instigated an argument with another girl, Nicole. Nicole, a non-popular girl, was enjoying the opportunity to put down those who were routinely mean to her. When an argument arose among the three girls regarding an outside factor not pertaining to the exercise, it seemed as if playing out this role reversal gave Nicole an inner strength that made her stick up for herself against Mirra and Erika. The argument was quickly dissolved when a Teen Camp staff member approached them, and removed Mirra from the group. The popular girls were, for the most part, able to treat the unpopular girls with respect throughout the exercise. They shed the qualities Lindsay claimed were necessary to retain their popular status. I was excited to see them positively interacting with girls they did not usually interact with.

Afterwards, the girls were asked how they felt about getting treated the way they did. Katie, on whom Mirra had inflicted such horrible treatment during the introduction exercise, said she loved getting asked what her ideas were, it made her feel good even if she knew people were doing it only because they had to I posed the question that if the popular girls did not like being treated badly, what gave them the right to treat someone else that same way? This question received a few lowered heads from the popular girls and glowing smiles from the non-popular girls. The point was proven. Giving the girls tools to make their own behavior apparent let them realize how hurtful they could be. The fact that all of them saw it simultaneously meant that no one girl had to be the martyr, or stand up and declare their behavior unfair and demand they all change their ways. Such a protest had never occurred before because, as Lindsay said, there was a fear that if one were to cross the popularity line and say something, she might lose her status and become unpopular, and what girl would take that kind of risk? Understanding the notion of how hurtful and frustrating being declared unpopular can be, one must consider that asking a girl who has made it to popular status to compromise that status means asking her to knowingly set herself for the same horrible treatment she has delivered to another girl. Again, this perpetuates the crisis of popularity.

In the next exercise girls' telling work revealed yet another connection between aspects of their lives and popularity. To deconstruct stereotyped behavior for girls, I read "Girl" by Jamaica Kincaid to the girls and asked them to write their own version. "Girl" is a mother's voice, as heard by her young daughter, explaining how to be female in their culture. The intent of this exercise was to confront stereotypes placed on them because they were girls. Each of them was able to list many demands made on them simply because they were girls. One non-popular girl, Vikki, with much insight, wrote her version of "Girl":

> *Wash your face with soap, not just water. Wash your hair every day.*
> *No kissing like the boy you are so bent on becoming. Iron your dresses.*
> *Talk softly and sweetly not yelling and laughing loudly like the boy you*
> *are so bent on becoming. No playing sports. Instead knit and do*
> *embroidery. Walk slowly. Don't run like the boy you are so bent on*
> *becoming. Be nice and sweet. Be ladylike around boys and*
> *I'll bet you get a good man. "But why do I need a man at my age?"*
> *So you can get married and have a good life.*

Like Kincaid's "Girl", these were instructions Vikki's mother had given her. Yet many of these items did not appear on the popular girls' list of demands. They were already part of their regular behavior, for example, they already washed their face with soap, which was not a priority for Vikki. She was not "well-taken of." Vikki did not comply with these rules, she liked playing sports and sweating, she did not like to sew, and she certainly did not like to be ladylike around boys. Therefore, her peers, even her own mother, to whom this was a disappointment, did not consider her popular. Upon meeting Vikki's mother, it was apparent that she was embarrassed by her daughter's physical appearance. Vikki must have been aware of this disappointment and embarrassment on her mother's part to write such a piece. This revealed a reinforcement of the expectations put on a girl by her adolescent peers, their mothers.

Each of these examples given reinforced the reason the workshop was created and, in turn, also lessened the barriers popularity put on the girls. This workshop, lasting only a few short months and each session not being very long, had made a visible difference. We had helped them grow by giving them tools to realize, on their own, how their behavior effects them and/or those they mistreat, along with the original intent of the workshop to help girls discover the wonderful possibilities that lie within each of them. The girls who spent just the summer at the workshop and no longer have exposure to this kind of work are more likely to lose sight of what they did learn. I find this not surprising because the pressure of this crisis-forming behavior is so intense, a long ago workshop will inevitably lose out. This is why I believe in the importance of understanding this crisis, so it can be addressed and deconstructed continually, rather than in selective workshops. Addressing the issue of popularity, which I have theorized as the crisis of popularity, gave the workshop the edge that completed the circle to understanding why many times girls do not see all they are made of. To give girls an early edge over what lies ahead for them is essential in combating this crisis that I have defined.

Production Scheduling of Flexible Manufacturing Cells

Jeffrey D. Erickson

School of Business
University of South Dakota
414 East Clark Street
Vermillion, SD 57069

Faculty Advisor
Bijayananda Naik

A Flexible Manufacturing Cell (FMC) consists of a small number of individual computer controlled machines which can perform a variety of metal cutting operations under the supervision of a central computer. In this research, four different heuristic scheduling approaches for FMCs were formulated and their performances compared. A sophisticated computer simulation model was used to simulate an FMC. The best scheduling approach for the FMC under consideration is recommended based on statistical analysis of the simulation data.

INTRODUCTION

The modern economy of the free world is driven by competition. Through competition, prices vary according to demand, new products are rushed to market, and costs are low in order to gain competitive advantage. When it comes to competition in manufacturing, the most successful organization is often the one that can best create economies of scale without sacrificing product variety. Manufacturers in the United States have traditionally relied on mass production of standardized goods to achieve economies of scale. However, achieving the flexibility of offering large variety of products requires small batch sizes.

One possible solution to the classic productivity and flexibility dilemma is the use of flexible automation. Flexible automation differs from traditional job shop or flow shop and combines the advantages of both. Many different types of flexible automation exist, ranging from the modest stand-alone Computer Numerically Controlled (CNC) machine to the complex Flexible Manufacturing System (FMS). Flexible Manufacturing Cells (FMCs) are manufacturing systems smaller in scope than the FMS and consist of several CNC machines linked by an automated Material Handling System (MHS). Flexible automation is at the heart of the concept of the "factory of the future" which allows for an increased production rate, a wider variety of products, and uninterrupted round-the-clock operation. In addition to increased productivity and high variety of products, the benefits of flexible automation include reduction in the number of machines and equipment, plant space, skilled labor for machining operation, work-in-process inventory, and associated costs.

Flexible automation, however, creates an entirely new set of problems. Due to the complex nature of the machinery involved, efficient scheduling methods must be developed for scheduling jobs on these machines. Since these sophisticated manufacturing systems are fairly new, appropriate scheduling methods for them are not readily available. As a result, traditional job shop scheduling rules are normally used for FMCs and FMSs. However, these computer controlled manufacturing systems require better scheduling approaches for efficient performance. The purpose of this research was to develop such scheduling approaches for an FMC. In the rest of this paper, we present the configuration of the FMC, a set of four heuristic scheduling approaches formulated in this research, the simulation experiments test the performances of the scheduling approaches, and statistical analysis of the simulation data. Finally, we recommend the best scheduling approach based on results of the statistical analysis.

THE FLEXIBLE MANUFACTURING CELL

The FMC modeled in this research is a cell with an arrival buffer, a central work-in-process (WIP) buffer, five CNC machines with an in-shuttle and an out-shuttle for each machine, and a robot for material handling. The layout of the FMC modeled is shown in Figure 1. The arrival buffer for the FMC was modeled with unlimited capacity to allow experiments with very high levels of buffer

966

congestion. The central WIP buffer inside the cell was modeled with a capacity to allow a maximum of 15 work-in-process parts in the cell (including the ones at the CNC machines) at any given time. The limited WIP capacity provided with the FMC is consistent with the goal of low WIP inventory in flexible manufacturing. The in-shuttle and the out-shuttle for a CNC machine were modeled with a capacity of one each.

The FMC modeled was assumed to process seven different part types. It is reasonable to assume that seven different part types provided sufficient degree of scheduling complexity in the simulation experiments conducted for this research. The number of operations for the parts varied randomly in the range from 4 to 10. These operations were selected randomly from a set of 15 operation types. The sequence of operation types for a part type was also determined randomly. Each operation could be performed by any of the five machines. The processing time (minutes) for each operation for a part was also specified.

The material handling robot serves the five CNC machines for transfer of parts from and to the machines. It does not transfer parts from the arrival buffer to the WIP buffer. This part transfer is handled by a separate transport device. The transport velocities of the robot for an empty move and a loaded move are not the same. For simplicity, it is assumed that the move times between machines, machine to WIP buffer, WIP buffer to machine, and machine to the exit station are the same, although the model has the flexibility of specifying separate move times. The computer code for the simulation model was developed by Naik (1995) using SIMAN/CINEMA modeling package.

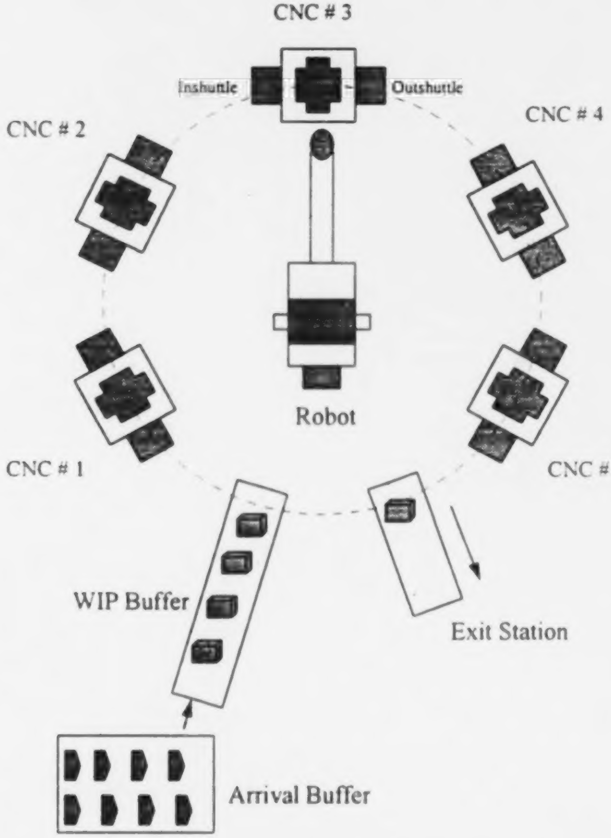

Figure 1. Layout of the FMC Used in This Research

FMC SCHEDULING PROBLEMS

FMC scheduling problems include determination of the sequence in which parts are input into the system, and determination of which operation of which part to begin processing on which machine at what time. The dynamically arriving parts have to be scheduled in an operation by operation basis or event by event basis in real time. Thus, real-time scheduling of an FMC essentially involves dispatching of individual operations of parts to available machines at any given scheduling point.

For the FMC studied in this research, the scheduling decision involves the following: selecting a job in the arrival buffer for moving to the WIP buffer when the space within the FMC becomes available as a result of finished jobs leaving the system, selecting a job in the WIP buffer to move to a machine when it completes its current operation and becomes idle, selecting a machine for a job when more than one machine become available to handle the same task. A set of four heuristic scheduling approaches were formulated in this research as described next.

H1 First-come-first-served (FCFS) rule was used for selecting a job from the arrival buffer and moving it to the WIP buffer. Earliest Due Date (EDD) was used to select a job from the arrival buffer to move to a machine that becomes available.

H2 FCFS was used to select a job from the arrival buffer. Shortest Processing Time (SPT) of the imminent operation was used to select a job from the WIP buffer.

H3 EDD was used to select a job from the arrival buffer and EDD was used to select a job from the WIP buffer.

H4 EDD was used to select a job from the arrival buffer and SPT was used to select a job from the WIP buffer.

If more than one machine became available for a job, the most underutilized machine was selected in each of the above four cases.

SIMULATION EXPERIMENTS

Simulation experiments were conducted for each of the four heuristic scheduling approaches described above. In addition, experiments were conducted for a benchmark case which used FCFS for the arrival buffer as well as the WIP buffer. Two performance measures were used to compare the scheduling approaches: mean flowtime and mean tardiness. The mean flowtime and mean tardiness values for the four heuristic scheduling approaches H1, H2, H3, and H4 were normalized with respect to the those for the benchmark case.

For each scheduling approach, experimental conditions were varied in 60 different runs for each case. Two different part type distributions, three different mean arrival time (exponential distribution), and 10 different random number streams (for the arrival process and part type distribution) were used resulting in 60 different combinations for each case. Each simulation run was carried out for a simulated shop time of 3 days (4320 minutes). A warm up period of 1 day (1440 minutes) was used and observations were recorded for 2 days (2880 minutes). Test runs indicated that these durations were appropriate.

STATISTICAL ANALYSIS OF DATA

A single factor ANOVA test was performed for each of the two performance measures: mean flowtime and mean tardiness. Four factor levels were used corresponding to the four heuristic scheduling approaches H1, H2, H3, and H4 described earlier. Type I error was specified at $\alpha=0.05$, and type II error was specified at $\beta=0.10$. Following an approach suggested by Neter *et al* (1990), the sample size of 60 was considered adequate in this research. The results of the ANOVA tests for the mean flowtime and mean tardiness are shown in Tables 1 and 2 respectively.

The results of the ANOVA test presented in Table 1 show that the performances of the four heuristic scheduling approaches are statistically equivalent. Since the F statistic is less than the critical value, there is no statistically significant differences in the average values of the mean flowtime. However, the results presented in Table 2 show that the average values of mean tardiness are not statistically equal since the F statistic is greater than the critical value. The lowest average value of mean tardiness occurs for H3 in this table.

CONCLUSIONS AND RECOMMENDATIONS

Simulation experiments were conducted using a computer model of an FMC. Data for the mean flowtime and mean tardiness performances of four heuristic scheduling approaches were obtained and analyzed statistically. No statistically significant difference was found in the mean flowtime performances of the scheduling approaches. The differences in the mean tardiness performances of the scheduling approaches were found to be statistically different. The mean tardiness performance of H3 was found to be slightly better than other approaches. Therefore, the scheduling approach H3 is recommended for the FMC studied in this research. Extensive further research with broader range of experimental variables is recommended for better understanding of production scheduling in FMCs.

Physical Attributions of Racial Stereotypes

Lori Dixon

Department of Psychology
State University of New York at Old Westbury
Old Westbury, New York 11568

Faculty Advisor:

B. Runi Mukherji

An experiment was conducted to investigate the effects of physical features on the priming of racial stereotypes. It was hypothesized that the presence of a picture would cue certain stereotypical racial schema in a participant and therefore he/she would respond more positively to statements consistent with a racial schema. Forty-six African American college students participated in the study. Participants were given a written text of a series of connected events that did not reference to any racial stereotypes. Half of the participants were given the text with a racially ambiguous picture attached the other half were not. Participants were given a questionnaire to asses their ability to recollect the events in the text. The questionnaire consisted of a variety of statements. The analysis indicates that there were no significant differences between the picture and non-picture groups as regards to the racially schematic statements. However, even in the absence to specific information, participants were more likely to reject the statements consistent with the Caucasian stereotype than the African-American stereotype $t(79)=2.23$, $p<.05$. These findings suggest that among African Americans, memory for events is influenced by racial schemas, possibly due to the nature, function, and consequences of prior social knowledge.

Racial stereotypes are a special case of interpersonal perception. They are usually simple, overgeneralized, and widely accepted (Brigham,1971). But stereotypes are often inaccurate. It is simply not true that all people with slanted eyes are Chinese or that all African Americans have big noses. Nonetheless, many social stereotypes concern highly visible and distinctive characteristics. These pieces of information are usually the first to be noticed in social interaction and can gain high priority for channeling subsequent information processing.

In 1954, Gordon Allport proposed that the stereotyping of racial and ethnic groups may be intrinsic to the cognitive system. That is, people over-simplify their experience by selectively attending to certain features of the information within the environment and by forming categories, concepts and generalizations to deal with vast quantities of available data. Tajfel and Wilkes (1963) found that identifying an individual as a member of a given group might engage the stereotype for that group, such that the individual's behavior would be interpreted in terms of the stereotype. For example, once you tag warm behavior as female, it may become motherly. The act of grouping persons into particular categories make the attributes of those categories especially salient.

The following experiment examines the role physical attributes play in the use of encoding information about people. Participants were given a written text of a series of connected events that did not make reference to any racial stereotypes. Participants were given a 40-item questionnaire to assess their ability to recollect the events presented in the text. Some of the items in the questionnaire were true statements, some were false statements, some were racially schematic statements, others were neutral statements that were equally likely to be consistent or inconsistent. It was hypothesized that the presence of a picture would cue certain stereotypical racial schema in a participant, and therefore he/she would accept statements consistent with a given racial stereotype.

METHOD

Participants

Eighty volunteers (46 women and 34 men) participated in the experiment. Some of whom were college students, others were adults from within one hour of the surrounding neighborhood. The average ages ranged from 18-60, (M=36).

Materials

Cover Task: The task required images to be formed of objects or people and rate the vividness of aspects of the images so formed. There were two groups of image items. Group 1: a dog, a radio, a house, and children in a playground. Group 2: a man, a clock, a supermarket, and a group of people in a hallway. The rating scale ranged form 1 to 5 , where a score of 1 implies an image as clear and vivid as normal vision and a score and a score of 5 implies no image formed at all. This task was used only as a cover task.

Story: A Day in the Life of Mr. X. A story was written to describe a series of events that could be describing the events in the daily life of a student, such as taking a quiz and shopping at the supermarket. The story was written in first person. A tape recording of the text was also used.

Questionnaire: A 40-item questionnaire was constructed. There were (1) 10 True statements that were rewordings of actual sentences that had occurred in the previous story; (2) 10 False statements that were contradictions of sentences that had previously occurred; (3) 10 Racial Inference statements were inference items related to the issue of racial schema. These schema-related inferences were of two types: either consistent with a Caucasian racial schema or consistent with an African-American racial schema. There were also (4) 10 neutral inference statements. Five of the ten inferences were positive, such that it was probable that it was a stated action or event in the previous story. The other five were inferences that were negative, were improbable or contrary to an action or event explicitly stated in the story.

Procedure

The subject was given the cover task before and after the story. The instructions for the cover task were told verbally. The experimenter explained that the experiment was a study of mental imagery, to asses one's ability to form mental images. They were then told to form mental images of the following objects or people and rate the vividness of aspects of the images formed. The range of the rating scale was explained. They were asked if they had any questions. If so, the instructions were repeated or paraphrased as often as necessary until he/she understood what was to be done. The subjects were then given the imagery items from group 1.

After that segment of the cover task was completed, subjects were then asked to listen and read a sequence of connected events and form mental images of said events. The experimenter placed the covered text in front of the subject. The text was not uncovered until a tape recording of the experimenter reading the text was activated. When the recording was finished, the experimenter stopped the tape recorder and removed the text from the subjects view. Subjects were then given the imagery items from group 2 of the cover task. The same instruction were told again verbally. Upon completion, the experimenter handed he/she the questionnaire. The instructions were read out loud.

> "Please read each statement carefully and indicate how each statement is consistent with the story that you heard and read. The scale goes from:-3 to +3. Where completely inconsistent would be -3 and completely consistent would be +3. A rating of zero was to be given if the statement is equally likely to be consistent or inconsistent with the statement." Two examples were given using a statement from the text. Then subjects were reminded, "Please note that this is not a questionnaire of how well you remember the exact information in the story. But the consistency to which your mental images coincide
> with story."

Each subject was not given a fixed time to finish the questionnaire. Subjects were run individually.

RESULTS

As shown in Table 1, the means and standard deviations of the types of statements illustrated that the subjects responded in accordance with the nature of the statements. Subjects tended to answer positively to the true statements, negatively to the false statements, and impartially to the neutral inference statements.

Table 1: Means and Standard Deviations of Types of Statements

	Total		Pitcure		Non-Picture	
Type of Statement	Mean	Std. Dev.	Mean	Std. Dev.	Mean	Std. Dev.
True	1.51	.61	1.40	.59	1.68	.62
False	-1.56	.69	-1.49	.84	-1.64	.42
Schematic Positive	.88	1.05	.68	1.08	1.12	.96
Schematic Negative	.61	.98	.69	1.05	.51	.89
Racially Schematic	-.35	.61	-.33	.66	-.38	.55

A t test was conducted, using the type of picture as a factor on the racially schematic statements indicated that there were no significant difference between the picture and non-picture groups. Also shown by Table 1, subject tended to reject or were indifferent to a racially schematic statement. However, it was found that the likelihood for subjects to reject the Caucasian schematic statements than the African American schematic statements was statistically significant, $t(79) = -2.23$, $p < .05$.

DISCUSSION

The hypothesis that the presence of a picture would cue certain stereotypical racial schema was not supported. There were no significant differences between the picture and non picture groups as regards to the racially schematic statements. Nevertheless, as illustrated by Table 1, there was a difference of True and Schematic Posistve statements between the picture and non-picture groups. The non-picture group responded more positively to the True and Schematic Positive statements. Participants who had not received a picture seemed to be more certian in their responses of what was consisitent and what was not consistent. The schema of the non-picture group was probably cued internally, by prior social knowledge, rather than cued externally, by the picture given. Also there was a difference between the neutral inference statements and racially schematic statements. Participants were able to recognize the neutral inference statements from the racially schematic statements, to classify which statement were probable and which just did not conform with thier racial schema.

The lack of a significant difference between the picture and non-picture groups, can possibly be attributed to the racial ambiguity of the picture shown. Participants denied the cue of a racial stereotype, perhaps because the cue itself wasn't adequately distinctive. If they had been shown a picture of a self-identified African American or a self-identified Caucasian, the cue would have been more pronounced and therefore, the categorization process more precise.

Even in the absence of specific information, surprisingly, participants were more likely to reject the statements consistent with the Caucasian stereotype than the African American stereotype. These findings suggest that among African Americans, memory for events is influenced by racial schemas. This can be explained by the fact that stereotypes structure the interpretation of ambiguous events so they can be assimilated to prior beliefs (Duncan, 1976). In a study by Duncan (1976), for example, Caucasian participants tended to describe an ambiguous shove as "violent" when the perpetrator was African American, but described the act as "aggressive" or "horsing-around" when the perpetrator was Caucasian. Secondly, stereotypes structure relatively unambiguous evidence in a self-confirming manner by the selective learning or selective remembering of events that corroborate the initial expectancies. (Duncan,1976).

Secord and Berscheid (1964), found that traits contained in the African American stereotype tended to elicit other stereotyped traits to a greater extent than they elicited non-stereotyped traits, regardless of the stimulus person's race. Tajfel, Sheikh, and Gardner (1963) showed that members of a stereotyped group are judged more similar on traits which are part of the stereotype than on traits which are not.

JULY, 1997

Foreword for the

Proceedings of the Eleventh National Conference on Undergraduate Research

University of North Carolina at Asheville
April 24-26, 1997

The University of Texas at Austin was pleased to host the 1997 National Conference on Undergraduate Research, affirming its commitment to excellence in undergraduate education and to the research experience in particular. Over 2100 students and faculty attended some 1500+ oral, poster and performing or visual arts presentations scheduled over April 24-26. A special feature of NCUR '97 was a series of more than 30 presentations by faculty members from all disciplines demonstrating the integration of research and teaching with the new technologies. These presentations were capped by a performance on Saturday night of "Ears and Feet," a concert of new interdisciplinary work by student and faculty composers, choreographers, dancers and performers from the UT College of Fine Arts. Electro-acoustic music and modern dance explored interactivity of disciplines and technologies by allowing dancers' movements to control electronic music and robotic lighting by way of a touch-sensitive computer dance floor.

President Robert M. Berdahl opened the conference quoting a Chinese proverb: "I hear and I forget. I see and I remember. I do and I understand." Berdahl praised the research experience as the most practical and potent method to provide students the perspective of inquiry, innovation and exploration as they prepare "for a future that is not so much known to be uncertain, but instead, certainly unknown." That facts and methodologies become obsolete in a world in which developments and advances occur with dizzying rapidity points to the importance of incorporating research activity into the undergraduate experience.

Dr. Berdahl also praised the student-faculty relationships that are fostered by the research process, congratulating the faculty mentor for serving the educational needs of the talented and motivated students by participating in the adventure of exploration and discovery, of cooperation and collaboration which characterize academic life.

Five distinguished plenary speakers addressed conference participants throughout the three days. Dr. Steven Weinberg, Nobel laureate in physics and professor at the University of Texas at Austin, challenged listeners to consider the future of science by posing the questions "The End of Science?". Dr. Robert Williams, Director of the Space Telescope Science Institute, dazzled the audience with the most recent images from the Hubble Space Telescope. From the vastness of space to the minute complexity of genetic research, Dr. Steven McKnight of the UT Southwestern Medical Center at Dallas introduced conference participants to the fascinating work being done in gene regulation and cell differentiation. Friday night's fete "Texas Culture Swing" featured, in addition to an outstanding sampler of culinary and musical styles of the Lone Star state, a mini-plenary address on the multifaceted aspect of Texas border cultures by Dr. Rolando Hinojosa-Smith, distinguished author and professor of Creative Writing. NCUR 97 closed with a resounding standing ovation upon conclusion of "The Challenge of Leadership" by Sarah Weddington, J.D., former Texas legislator and White House assistant, now author, lecturer and adjunct professor.

The University of Texas at Austin is proud of the privilege to share our campus for these few days with the distinguished group of students and faculty whose work is presented here in published form. We congratulate you for your accomplishments and encourage you to continue to participate in the challenge of research.

Susan Wells Howard, Chair, NCUR '97

PREFACE

The 407 papers published in these five volumes are representative of the approximately 1825 papers and posters presented at the celebration of undergraduate research that was NCUR '97'. The faculty, staff and students of the University of Texas at Austin are to be commended for making NCUR '97' such an enriching experience. The student authors deserve recognition for their hard work and for their persistence in seeing their research through to its final publication.

Special thanks are extended to Dr. Susan Howard, Ms. Kelly Johnson and other members of the NCUR '97' staff. Their help during the days of the Conference was invaluable. Many thanks also to the members of the National Board, who reviewed a large number of papers submitted to the Proceedings under time constraints. Their continued efforts to standardize has raised the Proceedings quality. This project would have not been successful without their assistance.

I would also like to thank the UNCA Editorial Board, who put in many long hours reviewing, checking and organizing papers, and Tracy Walker, and Adam Bradley, who did all the cutting and pasting necessary for these volumes. I owe a special debt of gratitude to Katherine Whatley, Tracy Walker and Mila Cleverdon for their support, encouragement, and mentorship during the entire process of organizing the Proceedings.

To all the students who submitted papers to the Proceedings go thanks for their participation and congratulations for their achievements. Your enthusiasm and achievement will serve as role models for the next group of student researchers - whom we look forward to meeting at the Twelfth National Conference on Undergraduate Research at Salisbury State University, Salisbury Maryland.

School of Engineering
California State Polytechnic University, Pomona
3801 West Temple Avenue
Pomona, California 91768

Faculty Advisor:

Dr. Julie Wei

The Main San Gabriel Basin Watermaster is sponsoring a research project at California State Polytechnic University, Pomona. Watermaster is faced with the challenge that a significant portion of its groundwater contains high nitrate concentration. An alternative water resources management strategy and nitrate removal treatment processes were evaluated. The alternative management strategy of using high nitrate water for non-potable uses proved to be economically infeasible. The team evaluated alternative treatment processes including the established processes (Ion Exchange and Reverse Osmosis) and state-of-the-art biological processes (BioDen™, Daisy Wheel In-Situ, Methylotrophic Fluidized Bed, and Autotrophic Sulfur Reactor). The preliminary cost analysis indicated that some of the state-of-the-art processes are very cost effective and promising. It is recommended that a demonstration scale facility be built and tested before a state-of-the-art process is adopted.

BACKGROUND

Nitrate is a significant groundwater contaminant. The sources of nitrate include animal waste, fertilizer and septic tank leachate. The health hazard of ingesting excessive nitrate has caused Methemoglobinemia (Blue Baby Syndrome) in some infants due to oxygen deficiency and possible suffocation. Healthy adults can tolerate higher nitrate intake. Some have suggested that nitrate may be converted to N-nitroso compounds. This can be associated with cancers of the stomach, esophagus, nasopharynx, and urinary bladder. The National Primary Drinking Water Standards set the MCL (Maximum Contaminant Level) for nitrate at 45 mg/l.

Water from the Main San Gabriel Groundwater Basin serves over a million residents. Water demand is mostly met by delivering about 245,000 acre-feet of groundwater annually. Throughout the years, a number of wells have been either inactive or abandoned due to high nitrate concentration found in the well water. The deficit in water supply of about 15,000 acre-feet has been supplemented with imported water. As the demand for water increases, new wells have to be drilled and inactive wells need to be reactivated. There is a financial incentive as well as necessity to use groundwater instead of imported water. The options of solving the nitrate problem through water resources management as well as pump-and-treat technologies in removing nitrate need to be investigated.

Existing records to identify potential users of high nitrate water were researched. There are a number of parks and large industrial users in the Basin that can utilize high nitrate water. Unfortunately, potential users are scattered throughout the Basin and mostly are a considerable distance from the high nitrate aquifer. Because a separate distribution system is cost prohibitive, solving the nitrate problem through water resources management is economically infeasible.

TREATMENT OPTIONS

The most common processes of removing nitrate from water supply are Ion Exchange and Reverse Osmosis. However, each has its advantages and drawbacks. Both generate concentrated wastes that pose waste disposal problems.

In certain cases, waste must be discharged to a designated brine line that may not be in reasonable reach of the water well. Even if a brine line is accessible, the costs to connect and to discharge can be high. Both processes are relatively expensive.

The new trend is to develop a biological process in removing nitrate. Heterotrophic bio-denitrification has been used in wastewater treatment for years. Heterotrophic bacteria require organic carbon as an energy source for respiration. Its use in water treatment has been restricted because water supply does not contain high organic carbon. Supplemental organic carbon must be added to the influent in order for significant denitrification to occur. The major concern for this type of process is the end products. The unused organic carbon has a potential to form DBP (disinfection by products) such as THMs and some other unknown halo-products that are health hazards. BioDen™, Daisy Wheel In-Situ, and Methylotrophic Fluidized-Bed are in the category of heterotrophic bio-denitrification.

Alternatively, autotrophic denitrification process is currently being developed. Autotrophic bacteria use carbon dioxide as a carbon source and oxidize inorganic matter for energy. The Autotrophic Sulfur Reactor is based on autotrophic bio-denitrification principle. The theory, advantages and disadvantages of each of the above mentioned processes are briefly discussed below.

Ion Exchange

Raw water is passed through a bed of resin. The resin has loosely attached anions such as chloride. In the ion exchange process the nitrate ion is exchanged for chloride. Eventually, the resin is "exhausted" because most or all of the resin are loaded with nitrate ions. Resin is then regenerated with concentrated NaCl solution to replace nitrate with chloride. The regeneration waste is high in TDS (total dissolved solids) and needs to be properly disposed.

Ion Exchange is a proven technology. The process is stable and the operation is simple. However, it does have the following disadvantages: 1) Brine disposal may be a problem, and 2) the product water contains high chloride.

Reverse Osmosis Process

Reverse Osmosis is a membrane process. Raw water is pressured through a membrane that does not allow the passage of molecules larger than water molecule. Nitrate along with other inorganic and organic molecules are removed from water. The waste contains concentrated contaminants and needs to be properly disposed. The process requires sufficiently high pressure to overcome the osmosis pressure and other pressure losses. The facilities include container, membrane, and pumps and control system.

Reverse Osmosis is also a proven technology. The process is stable and the operation is relatively simple. It also removes TDS. The major problem with Reverse Osmosis is membrane fouling. Pretreatment and membrane cleaning/replacement add complexity and cost to the process. It is also very noisy due to the constantly running high pressure pumps.

The BioDen™ Process

Raw water enters the *BioDen™* reactor towers, which contains naturally occurring, non-pathogenic bacteria. These bacteria are stimulated by the automatic addition of small amounts of nutrient (high fructose corn syrup) which causes the bacteria to respirate the nitrates into harmless nitrogen and carbon dioxide gases, which are vented into the air. The treated water then flows through slow sand filter which removes residual bacteria, organic matters and turbidity in the water. The vendor is currently investigating the effectiveness of replacing slow sand filter with rapid sand filter that is less costly.

Denitrification is carried out by numerous bacterial species found in soil and aquatic environments. The carbon source chosen for the BioDen™ process is High Fructose Corn Syrup (HFCS). It was chosen because of its low price, availability, non-toxicity, solubility in water and the ease with which it is degraded by a broad range of bacterial species. Furthermore, unlike some other carbon sources such as ethanol and methanol, HFCS is not flammable and can easily be stored.

Daisy Wheel In-Situ

In-situ bio-denitrification is an emerging technology to restore aquifers contaminated with nitrates. The research hypothesis is that naturally occurring denitrifying microbes can be stimulated by adding a stoichiometric amount of ethanol. Ethanol is used as the energy and carbon source. The end products are less toxic than that of methanol. Additionally, the nitrate removal rates should be fast enough to make this a practical remediation strategy in the contaminated aquifers. In order to denitrify deeper portions of the aquifer, a system called "Daisy injection system" will be utilized. The basic design consists of an extraction well (production well) surrounded by twenty injection wells arranged in a circular fashion. The injection wells will inject ethanol. Biological treatment takes place within the aquifer and vadose zone. It does not require a contactor structure. However, the in-situ process is difficult to control due to numerous variables involved such as physical and chemical soil characteristics. This is a technology still in the experimental phase but should be followed for further results.

Methylotrophic Fluidized-Bed Reactor

Methanol is used as the carbon and energy sources for heterotrophic bacteria. The fluidized beds are filled with graded sand with a uniformity coefficient of 1.46. Experiments show that excess methanol in the effluent is inevitable, and thus prompt to toxic by-product (mainly THM) during the chlorinating process. Therefore a GAC unit would be required to remove the excess methanol and VSS or VOC in the effluent before the water is disinfected with chlorine. The Methylotrophic Fluidized-Bed Reactor technology is quite complex, and thus requires intensive supervision. There is a small pilot scale plant currently operating in Europe, but this denitrification process is mostly in the research stage, so unexpected problems for a large-scale treatment plant can be potentially significant.

Autotrophic Sulfur Reactor

An autotrophic denitrification process is being developed at the Orange County Water District utilizing elemental sulfur as the energy source. The organism, Thiobacillus Denitrificans, oxidizes elemental sulfur using nitrate as the terminal electron acceptor. Carbon requirements are met by the assimilation of carbon dioxide, bicarbonate, and carbonate present in the groundwater. The end products of the reaction are nitrogen gas and sulfate anion. A variety of bio-reactor designs were tested successfully. Of these, a cone shaped reactor containing a partially fluidized bed of elemental sulfur granules (around a size 10 sieve) seemed to offer a significant advantage.

The advantages of this process include low TOC (total organic carbon) in the product water and a relatively simple system. However, the autotrophic process is slow compared to the heterotrophic process, thus, requiring a larger contactor. The process is new and its design criteria are still being developed.

PRELIMINARY COST ESTIMATE

The preliminary cost estimate is based on an 800 gpm demonstration plant. These cost comparisons are preliminary because some of the processes are still in the developing stages. The costs for Ion Exchange and Reverse Osmosis are based on previous project costs adjusted for 1997. The cost for BioDen is provided by vendor. The costs for the state-of-the-art biological processes are the team's best estimate with limited information.

The costs include construction cost, O & M (Operation and Maintenance) costs, and annualized total cost for nitrate removal facilities only. The construction cost has been annualized for 15 years at an interest rate of 7%. The processes are ranked from 1 to 6 for cost competitiveness with 1 being most cost effective.

Table1: Preliminary Cost Analysis

PRELIMINARY COST ESTIMATE

Processes	Ion Exchange	Reverse Osmosis	Auto-trophic Sulfur	BioDen™	Daisy wheel In-Situ	Fluidized Methanol Bed
Construction Costs ($)	$824,200	$1.7 Million	$1.05 Million	$1.5 Million	$761,000	$901,000
Annualized Constr. Costs ($/ yr)	$90,500	$189,725	$115,160	$171,720	$83,600	$99,000
O & M Costs ($/yr)	$57,500	$263,000	$102,000	$66,030	$143,460	$203,000
Total Annual Cost ($/yr)	$148,000	$452,725	$217,160	$237,750	$227,020	$303,000
Cost Competitiveness	4	6	1	3	2	5

CONCLUSION

Reverse Osmosis and Ion Exchange were determined as viable and proven treatment options. Three (Autotrophic Sulfur Reactor, BioDen and Daisy Wheel In-Situ) out of the four biological processes that were evaluated are very promising. All are state-of-art processes in various stages of development. BioDen™ is in a more advanced stage of development and Daisy Wheel has the potential to clean up a large area of aquifer economically. However, Autotrophic Sulfur Reactor may be the best. The process is simple, stable and does not appear to have the potential of producing harmful DBP. We recommend that the Main San Gabriel Watermaster monitor Orange County Water District's demonstration plant using Autotrophic Sulfur Reactor and to consider the development of a small demonstration plant using the BioDen™ Process in order to develop more reliable data.

OCCUPANT DYNAMICS IN STATIONARY AND MOVING VEHICLES SUBJECTED TO VERTICAL IMPACTS: AN EXPERIMENTAL STUDY

Peter D. Layson

Engineering Programs
Jacksonville University
Jacksonville, FL 32211

Faculty Advisors:

Toufic M. Hakim, Ph. D.
Orion P. Keifer, P.E.

While many studies have involved vehicle occupant dynamics and injury in lateral and line impacts, little research has been conducted to evaluate the effects of vertical impact and assess the potential for head and spinal injuries. This project deals with vertical impacts and provides data which should help develop severity-prediction models for furthering occupant safety. The impact is simulated by vertical stationary and moving vehicle drops of a single vehicle tire. Sensors placed at various points of interest in the vehicle and at the head region of the occupant monitored tri-axial accelerations of which profiles were collected via an onboard computer. The data was then analyzed based on the duration of impact and proximity to the point of impact, and was compared to data collected regarding vertical accelerations in common daily activities. The dampening ratios of a vehicle's chassis, seat, and of the human body are sought.

BACKGROUND

With the large number of transportation vehicles in use worldwide, one area of great concern is that of occupant safety. Over the last few years, this area has received considerable attention in the development of dynamic simulation models of vehicles' occupants. Automobile accidents alone caused 40,676 fatalities and over 3.2 million injuries in the United States in 1994. Medical costs relating to the direct care and rehabilitation of these fatalities and injuries exceeds $120 billion dollars per year. With automobile accidents being the leading cause of death for those between the ages of 1 and 34, the costs associated with production losses due to mortality is estimated to exceed $50 billion per year(Macinnis,1996).

Until recently, little research has been done to study the field of vertical accelerations sustained by humans; the majority of research has centered around lateral and line acceleration. The research in this study was prompted by the need for information concerning vertical impacts. The severity of such accidents had not been determined nor had models been developed to help give an understanding of the effects of various speed changes in vehicular accidents. In this project a series of low speed vertical stationary and dynamic impact tests were performed. It is expected that these tests will yield vital data to give a better understanding of the dampening effect in the specified areas of the vehicle and also in the human body. This data would also be useful in developing severity-prediction models of occupant injury (Macinnis,1996).

EXPERIMENT SETUP AND PROTOCOL

APPARATUS

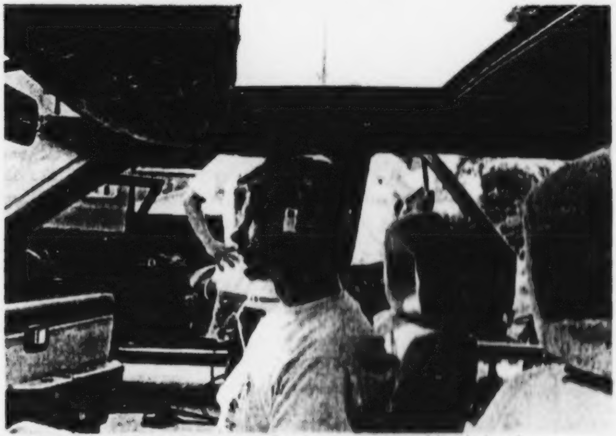
The apparatus used in the experiment included:

- An onboard computer data acquisition system.
- National Instruments VirtualBench Logger™ software (National Instruments, 1996)
- Two tri-axial piezoelectric accelerometers
- Peak accelerometers (2 arrays of 8) 2, 4, 6, 8, 10, 15, 25 and 30 g's
- Two video cameras, one still camera and video camera stanchion
- Accelerometer harness for the head (custom made in house)
- Lever system for drop test (custom made in house)

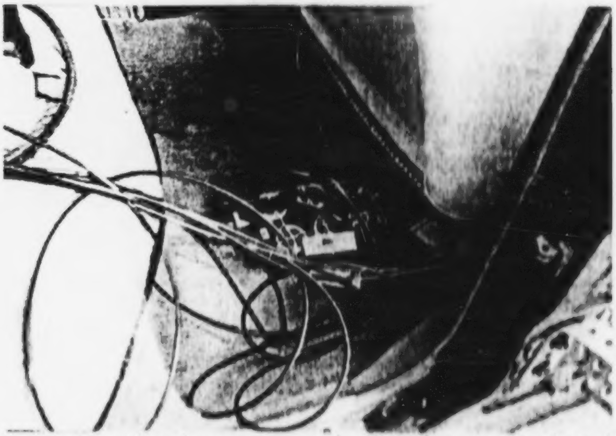
A detailed protocol was followed to guide the research and also to ensure the safety of the researchers and test subjects.

ACCELEROMETER PLACEMENT

There were two tri-axial piezoelectric accelerometer arrays; one was located under the passenger seat back and the other was located on the occupant's head harness (See Photographs 1, and 2). The two peak accelerometer arrays were located under the passenger seat back and in the trunk above the left rear tire (drivers side rear tire).



Photograph 1: Tri-axial accelerometer placement on test subject's head



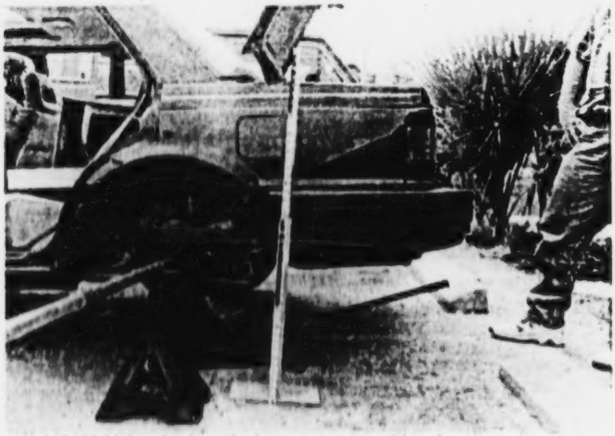
Photograph 2: Tri-axial accelerometer array and peak accelerometer array located below the seat back

STATIONARY SIMULATION

The stationary crash tests were set up to simulate the effects of an actual vertical impact on an occupant. The vehicle was raised from the left rear wheel (drivers side rear wheel) using a lever system (see Photograph 3.). It was then released from the heights 12", 18", and 24" to the bottom of the rear quarter panel allowing the vehicle to fall freely to the ground. The accelerations were measured on the three Cartesian axis at a number

BEST COPY AVAILABLE

of key points in the vehicle and on the head of the occupant for the duration of impact. A sample of the stationary data appears in figure 1.



Photograph 3. Vehicle raised on the lever system awaiting drop.

DYNAMIC SIMULATION

For the two dynamic simulations, the vehicle was prepared by removing all but two of the left rear wheel's lug nuts which were engaged approximately two threads. The vehicle was accelerated up to approximately 15 mph and was then turned right causing the wheel to be ejected off. The subsequent engagement between the tire and the vehicle resulted in the rear of the vehicle being first raised as the tire rolled partially underneath and then being dropped and slid to a rest position.

Data acquired from the onboard computer for both the stationary and the dynamic runs were used to read the accelerations at the point chosen. The dampening ratios of the separate components of the system were calculated using the geometry of the vehicle and the observed accelerations over the rear tire. Accelerations were then calculated at the seat position and compared to the actual observed values. The comparison allowed for the study of the effects of the chassis, seat and body on the absorption of impact.

RESULTS

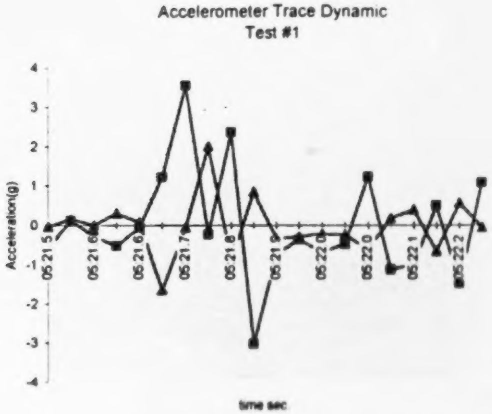

Figure 2. The vertical component of the two tri-axial accelerometers during the first dynamic impact simulation (▲ at head and, ■ at chassis)

ACCELERATIONS AND DAMPENING PERCENTAGES

Stationary Run	Peak a_{wheel}	Peak $a_{chassis}$	Peak a_{head}	Peak a_{person} Assuming no suspension
#1	2.1g	0.3g $damp_c$=71%	0.23g $damp_{c+s+b}$=78% $damp_{s+b}$=23%	1.05g
#2	3.9g	0.52g $damp_c$=73%	0.45g $damp_{c+s+b}$=77% $damp_{s+b}$=14%	1.95g
Dynamic Run				
#1	3.9g	1.40g $damp_c$=28%	0.6g $damp_{c+s+b}$=69% $damp_{s+b}$=57%	1.95g
#2	3.9g	1.33g $damp_c$=32%	0.53 $damp_{c+s+b}$=73% $damp_{s+b}$=60%	1.95g
Time Duration		$0.11 < \Delta t < 0.19$	$0.15 < \Delta t < 0.25$	

Table 1: Tolerance ≈ 11% on acceleration
c + s + b = chassis + seat + body

It was observed in both the stationary simulations and the dynamic simulations that the dampening effect in the seat and body was approximately 20%; that of the chassis was approximately 70%. The combined effect of the seat and body and chassis was approximately 75%. These numbers were within the ± 11% error calculated.

The peak acceleration experienced by the wheel well varied from 2.1g to 3.9g in the stationary simulation, but remained the same in both dynamic simulations. The suspension system of the vehicle is responsible for a_{wheel} exceeding 1g, but the research did not focus on the absolute value of the acceleration at the wheel, rather it focused on (a) the acceleration between the various points in the vehicle, and (b) the acceleration and duration experienced by the occupant.

The peak acceleration decreased considerably from the points of the wheel well, to the chassis and head. No accelerometers were positioned at the seat level to evaluate the dampening between the seat and head (this is currently being researched).

The duration of impact in all runs was less than 0.25 sec., with the head experiencing the longest duration at no more than 0.6g. Also, it is clear from the graphs that the shape of the acceleration curve at the head is much smoother and more spread out than its counterpart at the chassis and the seat. To put these forces into perspective, studies have measured the peak acceleration forces in whiplash motion from a simulated typical non-exaggerated cough at approximately 3.5g, a simple hop off a 8 inch step landing on both feet at approximately 8.1 g, and plopping passively backwards into an office type chair with a low back at approximately 10.4 g (AFSC, 1977). It was expressed by the test subjects that the forces experienced by the simulation could be compared to hitting a medium sized speed bump at approximately 15 mph (NASA, 1973).

By looking at the vertical accelerations from the simulations, a pattern of dampening was found for the system. These ratios given in percentages can be used to help approximate the amount of force experienced by an occupant. Further research is currently being conducted to separate the amount of dampening by the body. This information would prove beneficial in areas other than the study of vertical impacts.

ONGOING RESEARCH

An in-depth study to explore the dampening effect of the human body remains ongoing. A series of test composed of an exaggerated step and sit test will be used to examine the forces experienced by the human body. The test subject will be instrumented in four key points, these being the ankle, tail bone, base of the neck and head. This research will be used along with the previous data to help understand the effects of vertical acceleration and time duration on the human body.

ACKNOWLEDGMENTS

The author would like to express his appreciation to everyone at Applications Engineering Group, Inc., Jacksonville, FL, for making this research possible through funding and support.

SubzeroCam: Design of a World Wide Web-Based Digital Camera for Sunrayce 97

James A. Johnson

Department of Electrical Engineering
University of North Dakota
P.O. Box 7165
Grand Forks, ND 58202-7165

Faculty Advisor:

Richard R. Schultz

The purpose of this paper is to demonstrate a unique merging of solar-powered vehicle design and the Internet. Sunrayce 97 is a solar-powered vehicle competition in which undergraduate students from universities across the United States and Canada design and construct cars powered only by sunlight. These vehicles then race from Indianapolis, Indiana, to Colorado Springs, Colorado, over a ten day period in June. SubzeroCam is a World Wide Web-based digital camera that displays color images of North Dakota's first solar-powered vehicle, appropriately named "Subzero" for our renowned winters. Through an inexpensive digital camera connected to the Internet via a personal computer, SubzeroCam sends updated images of the UND Sunrayce laboratory to a web page in real-time.

Ultimately, the camera was developed to allow sponsors and other Sunrayce teams observe student members of the Society for Energy Alternatives (SEA) construct Subzero over the Internet at the World Wide Web address http://www.und.nodak.edu/sea/SubzeroCam/. Time-lapse movies, known as animated GIF's, were created from key days of construction, and they are also available on the SubzeroCam home page to download and view.

BACKGROUND ABOUT SUNRAYCE 97

Sunrayce is a biannual solar vehicle race that is open to all colleges, universities, and other post-secondary institutions across the United States and Canada. Organized by the National Renewable Energy Laboratory (NREL), Sunrayce is sponsored cooperatively by the Department of Energy, General Motors, and Electronic Data Systems (Sunrayce Headquarters Web Page).

Figure 1: Aurora II – University of Minnesota's Entry in Sunrayce 95

Solar vehicle racing is on the cutting edge of alternative energy development. These vehicles utilize composite structures, high efficiency solar cells, the latest in battery technology, high efficiency electric motors, as well as computer hardware and software to push these technologies to new limits. Students face the challenge of designing a safe vehicle to operate at highway driving conditions, powered by the same amount of electricity as that used by a hair dryer.

Vehicles must pass a strict scrutineering session two months before qualifying to be eligible for the competition. The qualifying session, held in either Michigan or Arizona, determines the fastest 40 vehicles which will participate in the actual competition.

Sunrayce 97 follows a 1,150 mile race route from Indianapolis, Indiana, to Colorado Springs, Colorado, and will be held from June 19, 1997, through June 29, 1997. Each day, participants race between 75 and 150 miles on a predetermined course using state highways. The cumulative racing time over the ten day event determines the final team standings.

On a broader scale, the objectives of Sunrayce are to stimulate interest in technical education and careers among students, promote energy efficiency and the use of renewable sources of energy, and raise confidence in alternative energy methods that make fewer demands on the environment.

BACKGROUND ABOUT THE SOCIETY FOR ENERGY ALTERNATIVES (SEA)

The Society for Energy Alternatives (SEA) is the newest student engineering organization at the University of North Dakota (UND) (Society for Energy Alternatives Web Page). SEA's mission is to promote energy conservation and environmental awareness through its efforts in Sunrayce. The team consists of approximately 40 members, primarily in the mechanical and electrical engineering disciplines. The different backgrounds and experiences of the members contribute to the potential success of the team.

As a first year team, several obstacles inhibited the progress of SEA's solar vehicle. The most outstanding of these was the cost incurred for design and construction. Corporate and individual sponsorship was the answer to this dilemma. To date, SEA has managed to capture the attention of many corporations, UND alumni, and professors, and the Society has raised over $100,000 in monetary, expertise, and material donations.

Currently, the solar car is in the midst of construction. Each of the design teams (power systems, body, suspension, and chassis) set up for the project have spent incredible amounts of time designing their aspect of the car. A graphical rendering of "Subzero," appropriately named for our renowned North Dakota winters, is shown in Figure 2.

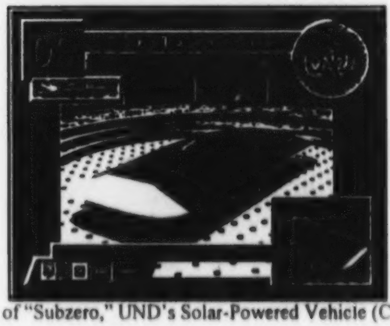

Figure 2: Rendering of "Subzero," UND's Solar-Powered Vehicle (Courtesy of VSAERO)

DESIGN AND IMPLEMENTATION OF SUBZEROCAM

An open philosophy was adapted early on by SEA team members in the development of Subzero. Being a first year team, many seemingly unanswerable questions arose which could be addressed only by teams with prior experience. Most teams were hesitant in doling out help, for they viewed Sunrayce as a serious competition between the colleges and universities involved.

To hopefully open the doors of communication among the teams, SubzeroCam was developed for the University of North Dakota's solar-powered vehicle project at the World Wide

Web address http://www.und.nodak.edu/sea/SubzeroCam/. This allows our corporate and individual sponsors and other Sunrayce teams to observe the construction of Subzero over the Internet. Through an inexpensive color digital camera, the Connectix Color QuickCam™ (Connectix Corporation Web Page), scenes of the solar-powered vehicle laboratory were collected as still digital images and image sequences during days of high activity in the work space.

Digital Camera Hardware and Software Interface

A unique aspect of SubzeroCam is that it bridges the gap between a personal computer and a UNIX station. The Connectix QuickCam™ is used on the personal computer for image and video acquisition, and a separate UNIX machine is used to support the SEA web pages.

The Connectix Color QuickCam™, shown in Figure 3, offers a quick and easy installation. The camera User Guide (Connectix Corporation, 1996) leads the user through a simple Windows 95 Plug and Play installation of the hardware (including only the digital camera with no internal computer cards) and software.

Figure 3: Connectix Color QuickCam™

The camera's software allows for easy adjustment of image size and quality. Although the fluorescent lighting conditions within the laboratory shown in Figure 4 were poor, adjustment of the brightness, hue, white and black levels, and saturation help produce an excellent image. Image size was set to "Half" (320x240 pixels) to maximize overall image size and minimize the file size on the computer hard drive. The Color and Sharpness features were maximized to attain the best possible image. With these above settings, the average JPEG-format file was 12 kilobytes in size. Focusing was performed by the adjustable ring on the outside of the lens.

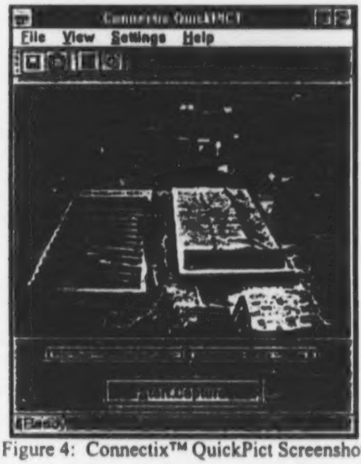

Figure 4: Connectix™ QuickPict Screenshot

Other features include the capability to take pictures automatically and at varying time intervals with the auto capture options. This allows the camera to be set up in basically two modes: single or multiple image capture. Normally, the single capture mode is desired, essentially to conserve space on the hard drive of the computer. After choosing a time interval between every picture, a file name must be chosen. In Figure 5, the interval time was set to 5 minutes, and the software was set to save the single image each time as "subzero.jpg." On key days of vehicle construction, digital video sequences were created by changing the camera set up so that an image was captured every 5 minutes and then saved as a unique file name. For the multiple image capture mode, the file series must be indicated; e.g., the sequence "subzero.jpg" automatically saves the images as subzero1.jpg, subzero2.jpg, etc.

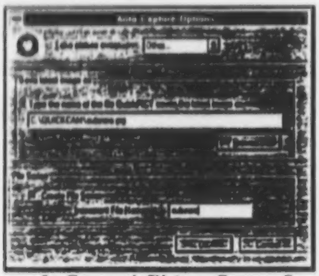

Figure 5: Connectix™ Auto Capture Screen

This digital camera was connected, via the parallel port, to a personal computer (486/33 MHz) running the Windows 95 operating system. With the use of a program called Microsoft Front Page, downloadable at http://www.microsoft.com, the personal computer was set up as a web server (FrontPage 97 Web Page). This allows the computer to be connected to the campus network via an Ethernet connection. This configuration has its own allocated Internet Protocol (IP) address and web site name.

The most difficult problem dealt with getting the "subzero.jpg" image from the personal computer used for image acquisition to the UNIX server where the Society for Energy Alternatives web pages reside. With the described set up, a link can be set within the HTML code of the SEA web page to the images saved by the digital camera software.

The final result of the SubzeroCam web page containing the image "subzero.jpg" is shown in Figure 6 as viewed by the Netscape Navigator© web browser. To date, the visitor count is over 8,000, with a goal of 10,000 hits by May 1997.

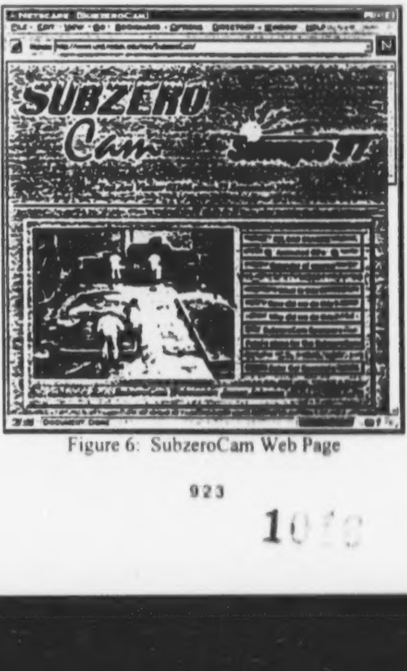

Figure 6: SubzeroCam Web Page

Animated GIF's: Generation of Digital Video Sequences

SubzeroCam was originally inspired by another Internet camera at the University of Notre Dame known as the DomeCam (DomeCam Web Page). Although similar in nature to SubzeroCam, it is a completely UNIX-based camera that views the golden dome of the administration building on the Notre Dame campus. Images are captured every five minutes, and at midnight the images are compiled to create a 24-hour time-lapse movie in the MPEG-format. The advantage of the DomeCam configuration is that the UNIX script was developed to automatically create time-lapse movies in the commonly accepted MPEG digital video format.

For SubzeroCam, a similar approach was taken to generate digitized video sequences. Time-lapse movies, known as animated GIF's, were created from key days of construction. With the use of a shareware program called the GIF Construction Set for Windows, downloadable at http://www.mindworkshop.com/alchemy/alchemy.com, a series of images can be concatenated to create a digital video sequence (GIF Construction Set for Windows Web Page). A built-in wizard guides the user through this process with relative ease. Essentially, it lets you choose the images to be used in the sequence and then prompts for the desired time interval between each image. Animated GIF's are viewable in many web browsers, including Netscape® and Microsoft Explorer®. Several movies are available on the SubzeroCam home page to download and view.

The challenge of using this shareware program was making sure that the individual still images were in the correct sequence. Since the file series ends with numbers, the file subzero1.jpg will immediately be followed by subzero10.jpg, placing images 2-9 out of sequence. The result of placing many images in order quickly becomes a tedious process. Attempts are still being made to automate this process, preferably on the personal computer side.

CONCLUSION

An inexpensive World Wide Web-based digital camera was successfully created to allow sponsors and other competing Sunrayce teams watch the construction of the University of North Dakota's first solar-powered vehicle. With the use of the Connectix QuickCam™ and its software, SubzeroCam was designed and implemented. This camera captures digital images of the laboratory work space where Subzero is being constructed, and those images are continually updated to a specially designed web page located at the address http://www.und.nodak.edu/sea/SubzeroCam/. Animated GIF's were also created from key days of construction and are available to download and view.

Proceedings — NCUR XI (1997)

Using Java for Computational Electromagnetic Scattering

Jared Martin

Department of Aerospace Engineering
Pennsylvania State University
233 Hammond Building
State College, PA 16801

Faculty Advisor:

Dr. [illegible]le Long

ABSTRACT

Java is a new and progressive language, which, to this point, has been used mostly for simple purposes, such as providing interactive graphical user interface (GUI) components on web pages (Lemay, Perkins, 1996). However, the potential of the Java language has yet to be realized. Its platform independence and ability to utilize the largest network in the world, the world wide web, will one day allow a standard personal computer to have the same power as a super computer, such as a Cray. This project explored that potential, examining the ability of the Java language to perform a large number of floating point operations by computing a computational electromagnetics code. This code, employing the Finite Difference Time Domain method for electromagnetics, was modeled after a Fortran version written by Dr. Raymond Luebbers, Dr. Karl Kunz, and John Beggs, of the Pennsylvania State University (Kunz, Luebbers, 1993). Output from both codes was compared and proved identical. Run-time performance was also examined, and the Java code was slower. However, beta versions of Java compilers were sampled (but cannot be published due to a non-disclosure agreement) and proved much faster than their predecessors, only slightly lagging behind Fortran run-times. Additionally, since computational science relies on enhanced visualization techniques, Java's graphics capabilities were explored in the project. This feature, not provided by the Fortran language, was examined by animating the scattered electromagnetic field. While the animation is very coarse, it is expected that Java's graphics capabilities will follow an evolution similar to current video game systems. This complete code can be found at http://www.personal.psu.edu/lnl/fdtd.

BACKGROUND

Fueled by its application to multiple scientific disciplines and numerous industrial applications, computational electromagnetics (CEM) is a growing field. For example, oceanographers rely on CEM methods to analyze electromagnetic backscattering from the ocean bottom. Organizations such as NASA rely on CEM methods to inspect electromagnetic wave transmissions from space and from antennas. While there are several computational electromagnetic methods in existence, one of the most widely used and increasingly popular is the Finite Difference Time Domain (FDTD) method. Besides being much simpler than other computational methods to grasp and implement as code, the FDTD method is able to effectively model complex geometries and most material types. This allows for a broad range of capabilities: the ability to analyze scattering and radiation problems involving wires and plates, to model microwave propagation through inhomogenous biological materials, and to analyze electromagnetic backscattering from aircraft, such as in stealth technology (Kunz, Luebbers, 1993). The question, then, is given the increasing need for effective computational electromagnetics, and the growing popularity of the FDTD method, what is the most advantageous way to implement this method? This project explores that question by examining the advantages of the Java language applied to computational electromagnetic scattering.

INTRODUCTION

Java is extremely attractive for computational science (not just electromagnetics but fluid dynamics as well) for three main reasons. First, Java has several inherent characteristics, such as threads, which are well supported by many of today's powerful processors, such as the SMP. Second, Java naturally understands networks, and can transmit through the largest network in the world, the world wide web. And, because Java is object oriented, this feature allows Java to distribute object models to multiple machines connected to the network, and for those processes to run in parallel. Currently, Java does not allow message passing between parallel processes, but it will in the near future. Third, Java's graphics capabilities, while primitive at this point, allow for enhanced visualization of electromagnetic (or fluid dynamic) fields. Visualization of such fields in the past has relied on static images viewed in discrete time intervals-- much like tracking a moving ball with multiple pictures from a still camera. However, the Java language allows for visualization of these fields over a continuous time interval-- like tracking the same moving ball with a video camera instead of a still camera. This ability to animate and display physical processes in nature has further implications for educational institutions, providing excellent visual aids for professors and students of engineering and science disciplines.

Furthermore, a significant attraction of Java is its ability to implement very appealing GUIs, or graphical user interfaces (Lemay, Perkins, 1996). Whereas most programming languages require the user to "hardwire" code parameters, the Java language allows the user to manipulate the same parameters with buttons, scrollbars, menus, etc. This dramatically increases the usability of the code.

METHOD

Approach

The FDTD method has multiple capabilities (analysis of currents, power density, interior coupling, scattered fields, etc.) for a variety of electromagnetic devices (such as lasers, microwave, radar) and for a variety of systems responding to that stimuli (aerosols, humans, aircraft, etc.). This project will analyze the FDTD capability to model the scattered field and radar cross section from an airplane wing responding to a radar wave.

These factors were chosen based on a unique problem posed to current stealth technology research, stealth helicopters. The design of most stealth aircraft involve optimizing both the geometry of the aircraft and its material. However, the airfoil geometry of the helicopter blade can not be altered much, since it is the characteristic airfoil shape which produces the required lift. Therefore, the design of stealth helicopters must rely on the optimization of the material properties of the helicopter blade. Because the FDTD method can analyze complex geometries and most penetrable dielectric and magnetic materials, the FDTD approach is a good candidate for examining these material properties.

Algorithm

Implementation of the FDTD method for electromagnetic backscattering requires six main steps:

1. Define the problem space cell size
2. Construct the target object
3. Define the size of the time step
4. Analytically specify the incident field
5. Perform the computation on the scattered field
6. Apply the boundary conditions.

The problem space, including the geometry of the target object, is defined in rectangular cells with dimensions of no more than 1/10 the wavelength of the incident field. Secondly, the target object is constructed in Yee cells (Yee, 1966). Although building the object in rectangular cells does produce some staircasing of the geometry, accurate modeling can still be made by minimizing the dimensions of the Yee cells. The time step for iterating the computation must be chosen such that the electromagnetic waves do not propagate through more than one cell per iteration. This is known as the Courant stability condition, and the time step is usually chosen as the smallest cell dimension divided by the speed of light. Fourth, the incident field must be defined. This is an analytical specification, a key advantage of the FDTD method, and the incident field is chosen as a Gaussian pulse. The parameters for this step consist of the pulse amplitude, frequency, and width in time steps. The fifth step involves the advancement of the x, y, z component of the scattered electric and magnetic fields. Lastly, some outer radiation boundary condition must be applied to account for the usual boundary effects in computational modeling. This project used a second order Liao boundary condition method, which is a standard method in computational electromagnetics.

The run time of the algorithm is dependent on the dimensions of the 3-D problem space and the maximum number of floating point operations per second (FLOPS) supported by the computer on which the code runs. For N number of cells in the problem space, 6 components per cell (Ex, Ey, Ez, Hx, Hy, Hz), 10 operations per component, and T time steps, the run time is approximately 60 x N x T divided by the maximum number of FLOPS on the machine.

Implementation of Java

Because of the large number of computations required for this method, and for other computational methods, parallel processing computers are often used to allow for larger problem spaces (Ahuja, 1995). Most parallel processors will only accept non-object oriented languages such as Fortran and C. However, to view computational fields, it is preferable to incorporate the most modern graphics capabilities. More and more, modern graphics technology is using object oriented software, for example the Virtual Reality Modeling Language (VRML). It becomes useful, then, for computational science to follow a similar path, such that modern implementations of computational methods are compatible with modern graphics technology. The disadvantage of object oriented computational methods, currently, is that they are often not supported on parallel processors, and thus are restricted to the size of the problem space they can generate. However, object oriented coding does possess a multi-threading feature, which allows for simultaneous execution of separate tasks. So, for example, six separate threads could simultaneously compute the scattered electric and magnetic fields in the x, y, and z directions. The current restriction on this feature is that message passing between threads is not supported, so the processes must be independent of each other. Methods for message passing, though, are quickly being developed, and will make Java even more efficient-- perhaps allowing clusters of standard PCs to mimic a supercomputer.

It is for this reason that the Java language was chosen for this project. Java has a networked based architecture and is platform independent. Therefore, individual threads can run on separate processors. Also, Java can be transmitted across the internet, so the processing power is massive. Furthermore, Java is directly compatible with VRML, so it provides enhanced visualization. Multi-threading and VRML, however, were not investigated at this time. Instead, the project examined Java's run time speed in performing the computation, accuracy of the results, and Java's ability to animate those results. The Java code for this FDTD method was modeled after a Fortran version designed by Dr. Raymond Luebbers and Dr. Karl Kunz of the Pennsylvania State University (Kunz, Luebbers, 1993). Run time speed and results were compared between the Fortran and Java code on multiple platforms.

Design

The URL for this applet is http://www.personal.psu.edu/lnl/fdtd , and the design of the code is illustrated by the flowchart in figure 1. The modules called within Fdtd class are inter-meshed, passing static variables or instance variables between each other. ImageFoil, Fdtd, Animate, and Graph are all pop- up windows within which the computations are performed and/or the displays generated. Because the computation is performed within a pop- up window, multiple computations can be performed simultaneously, assuming the user machine has sufficient memory to handle the data storage.

RESULTS

Figure 2 depicts the results of the run-time comparison between Java and Fortran for the FDTD code. This graph is for a 20x20x20 cell problem space with 200 time steps, approximately 96x10^6 FLOPS. A more comprehensive comparison of run times for various MFLOPS between Java and Fortran can be found at the Java Linpack web site, http://www.netlib.org/ benchmark/ linpack.java. While Java does lag behind Fortran, the Java compilers are rapidly becoming more effective (unfortunately, the beta compiler can not be named because of a non-disclosure agreement). Whereas Fortran has been optimized over the past 20-30 years, Java is only a few years old, yet is developing and evolving at a much faster rate. Based on the Java Linpack data and the results obtained in

this project, it is evident that Java is quickly becoming comparable in run-time to an established language such as Fortran. This provides supporting evidence for the effectiveness of Java applied to computational electromagnetic scattering.

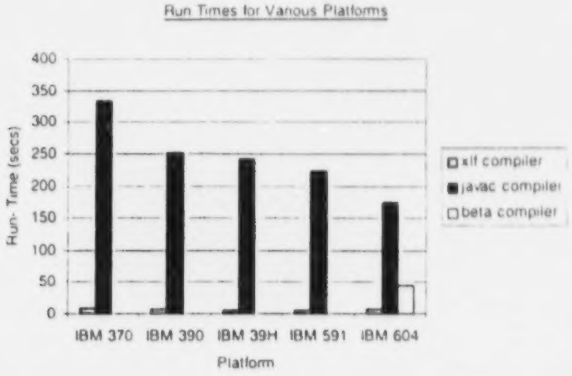

Figure 2. Run-time comparison between Fortran and Java on various platforms

Figure 3 displays the I-J plane cross section of the scattered electric field in the x direction at time step 30 for the same conditions as figure 2. The Fortran output is depicted by diamonds (from the Fortan "xyzIJ.dat" data file) while the Java output is depicted by dashed lines (from the Java "exsIJ.dat" data file). The similarity of results is very promising. Because different compilers handle floating point operations differently, and because Java is significantly less developed than Fortran, this level of accuracy was not expected.

CONCLUSIONS

The results of this project provide supporting evidence for the use of Java for complex tasks such as computational electromagnetic scattering. Java has demonstrated 1) an ability to produce accurate results at a high level of precision, 2) potential for run-time performance comparable to an established computer language, 3) because of its multi- threading capabilities, a potential for parallel performance-- perhaps in the future, comparable to parallel supercomputers (Ahuja, 1995).

There are a few suggestions for improvements on this code. For example, the

ElecMagFld.class module currently contains the six methods which need to be performed

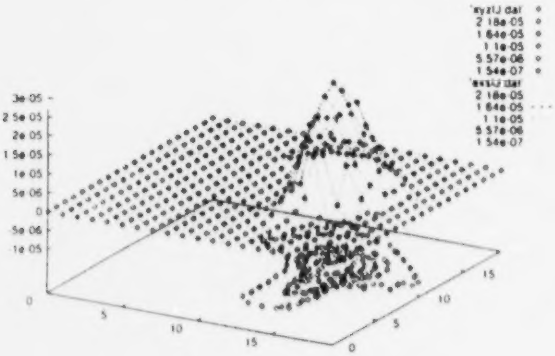

Figure 3. Scattered Ex field for a single time step

on the electric and magnetic fields. Because these methods can be run independently, without communicating between each other, this class could be divided into 6 separate classes implementing threads. The threads perform the six methods in parallel, and each class containing the thread would extend a parent class containing the field values. This would decrease the run time by an order of magnitude. Caution must be taken, however, that other methods or threads within the computation do not perform their operations prematurely. For example, the LiaoBC.class must not perform operations before the E field methods have been performed. Additionally, since the operations are performed within a time step loop, the loop must not be able to advance until all operations for that iteration have completed.

Further, improvements in graphics can be made in the animate.class module. Hopefully, with advances in such languages as VRML, the ability to display an animated 3D electromagnetic field will become a reality. Also, Java needs to incorporate an animation routine which does not simply call a repaint method within a loop. For a large number of small pixel cells (e.g. 40x40 grid of cells with dimensions of 10 pixels), a "curtain" effect develops.

The future of Java looks very promising. With improvements in data parallel and message passing features, and graphics capabilities, Java may become the dominating computer languages. A worthwhile URL to visit is http://www.javaworld.com/javaworld/jw-01-1997/jw-01-dampp.html, which discusses a Distributed Applet Massively Parallel Process (DAMPP). This DAMPP system performs a ray tracing computation by using Java's network feature to allow the computations to run in parallel on multiple machines connected to the world wide web. However, this computation does not involve any message passing between the threads, which many computational methods require. This method is tribute, though, to the potential of the Java language.

Radar backscatter coefficient records for the TOPEX/Poseidon radar altimeter were found to possess abnormal spikes in amplitude. It was postulated that these high returns were somehow related to a lack of surface roughness providing a high pulse energy return. Global occurrence of the spikes was examined and ocean surface characteristics at the geographical location of the spikes were investigated. A correlation study was made of ECMWF wind forecasts with backscatter and other data products. Negative correlation was found, implying low wind conditions cause a large majority of the phenomena. Surface slicks, both biogenic and man-made, were also implicated. Abnormal backscatter readings add noise to the sea surface height product, important to global change calculations. Current editing guidelines seem to compensate for the anomaly, which should be considered in the next generation of altimeter algorithms.

INTRODUCTION

Radar altimetry has become a major tool for measuring global ocean circulation with its development from GEOS-3, Seasat, Geosat, ERS-1, TOPEX/Poseidon, to ERS-2. The radar altimeter yields an accurate measurement of the height from the instrument in orbit to the ocean's surface. This is done by timing the two-way travel of a microwave radiation radar pulse from altimeter to nadir (the spot directly below the satellite on the ocean's surface) and back. The fundamental measurements are significant wave height (swh), sea surface height (ssh), and backscatter coefficient (σ^0), which is derived from the radiation scattered back to the satellite. SSH is found by applying precision orbit data, earth's geoid, tidal and atmospheric corrections to the pulse's travel time.[1] SWH is calculated from the slope of a pulse's waveform. The method of pulse altimetry is documented by Chelton, Walsh, and MacArthur.[2]

The need for calibration is obvious and a detailed strategy for the calibration of radar altimetry missions is outlined by Koblinsky et. al.[3] As mentor, Koblinsky assigned the author the task of investigating apparent 'spikes' in the TOPEX σ^0 data. Before detailing previous work on the spikes, we will look at σ^0 itself.

The radar backscatter, σ^0, is derived from the instrument specific automatic gain compensation, AGC. The AGC determines the attenuation that is applied to the returned signal to keep a constant output power. This is described in better detail by Rapley[4] and Chelton et al.[2] Each particular instrument has its own AGC. After several instrument specific constants are subtracted, a measure of the σ^0 is derived. This backscattered power depends on the sea surface roughness, which is dependent mostly upon wind speed.[5]

George Hayne and Dave Hancock did the initial work on σ^0 spikes which is documented in part in the Observational Sciences Branch WWW site.[6] They refer to the data anomaly as σ^0 blooms. As suggested by Dr. Kevin Arrigo, they will be referred to here as σ^0 spikes. Blooms can refer to plankton blooms, which are themselves a possible cause of σ^0 spikes. Hopefully this will circumvent any confusion from mixing biology and engineering.

Originally, scientists from Johns Hopkins Applied Physics Lab queried Hayne and Hancock about fluctuations in TOPEX Vatt, which is a measure of satellite attitude. If Vatt is zero the satellite is pointed straight at nadir. A subsequent investigation led them to notice regions of the AGC where the response rose by 6 dB or more, i.e. the spikes. They found it was not an instrument problem, and thus concentrated on the σ^0.

The spikes are marked by local increases in σ^0 to above 12 dB in the Ku band, and above 16 dB in the C band. They are found in all cycles and persist for up to tens of seconds. The TOPEX dual band altimeter allows scientists to calculate the ionospheric correction from the difference between the two bands. The waveform based attitude estimate (Vatt) increases during a spike to a limit of 2.55 degrees, signaling Vatt out of normal bounds. The spacecraft's actual attitude changes very slowly. These attitude out-of-bounds markers are caused by the σ^0 altering the waveform amplitude. This causes the trailing edge to fall off faster than the algorithm is programmed to accept. Refer to Chelton, Walsh, and MacArthur[2] for how the waveform is derived and for a look at a sample waveform. It is emphasized that the satellite is not actually aimed away from nadir during a spike. The spikes generally occur at low SWH, but can be found at values up to 4m. Such σ^0 spikes have been seen in Geosat[6] and ERS-1[7] data. Guymer and Quartley also cite the importance of σ^0 in deriving correct sea surface topography.[7]

In an initial investigation of one full cycle (10 days), Hayne found the spikes to affect 5% of the overall data.[8] Spikes could affect SSH measurements in two ways. An anomaly in the ionospheric correction (tied to a spike) would cause an error in the range, since ionospheric correction is a constant used in finding the range. If the σ^0 spike is linked to an increase in sigma height (sigh: the 10/sec rms of SSH), this would indicate the range value is not as reliable during a spike. A spike could also tell us something about the ocean's surface, perhaps indicating a slick or calm area.

METHODS

We desired to make a correlation analysis of the σ^0 spikes and actual ocean surface conditions. After discussion with Hancock, Hayne, and Koblinsky, it was opted to use a conservative value of 16 dB K-band to demarcate a spike in my investigation. In retrospect, 13.5 dB would have been a more thorough value. However, the one used saved computing time and still provided plenty of data.

We know ocean surface roughness, which is due to wind energy, is the main cause of radar backscatter. Capillary waves are believed to begin at wind speeds above 4 m/s. It isn't until wind speed reaches 5 to 7 m/s that the ocean's surface begins to experience wind loading and the consequent increase in roughness.[9] Surface slicks, whether biogenic (caused by plankton blooms or some biological process) or manmade (such as oil), tend to decrease surface roughness. Thus we expect σ^0 spikes will occur under low wind conditions or when the altimeter tracks a slick, since that is when the ocean's surface is calmest and smoothest.

The first step was to analyze all the material available on the OSB Web site.[6] which includes histograms and a movie of bloom occurrence. With Kenny Rachlin, occurrence maps were generated using TOPEX tracks 11 to 100. We saw a higher rate of occurrence in the tropical latitudes and the doldrums. Spikes that were possibly caused by formation of sea ice in higher latitudes have been edited out of the GDR. We also generated AGC maps for both bands and K-band σ^0 maps for the individual cycles 11-100. These were examined for temporal and spatial patterns.

Prevailing winds and climate maps were analyzed. Monthly maps of SSMR (side scanning microwave radiometer), ECMWF (European Center for Medium range Weather Forecasts), and COAPS were available.[10,11] These various wind products all showed low winds in the tropics and high winds (>7m/s) in areas where spikes were less frequent.

All summer I searched for a synthetic aperture radar (SAR) image of a surface slick that had also caused a spike when TOPEX passed over. A surface slick shows up as a black patch when viewed by SAR. This was not an easy thing to find. However, one did turn up in the JPL home pages.[12] This will be discussed further in the results section. The difficulty of finding a match between a satellite overpass and a shipboard observation, which was also tried, is discussed by Srokosz and Guymer.[13] In order to match TOPEX σ^0 spikes with biological slicks one could use coastal zone color scanner (CZCS) data, but none was available for the relevant time period.

It was decided to concentrate on one section of ocean that held a high number of σ^0 spikes. The test area covered -20 to 20 N latitude and 100 to 180 E longitude, in the western tropical Pacific, shown as an occurrence map in Figure 4. I downloaded all the σ^0 data for every TOPEX track in this area from cycles 11-100. This corresponds to late 1992 through the end of 1994.

The only wind data which was readily available was ECMWF gridded u and v wind component forecasts. This is from a 2.5 by 2.5 degree grid and calculated every twelve hours at midnight and noon. With the help of Christine Boone I downloaded the data in the test area and interpolated the wind component onto the TOPEX tracks, thus getting wind speed. The ECMWF claims an accuracy of just over 90% on their forecasts.[14]

I also downloaded the TOPEX C-band σ^0, ionospheric correction (ionocor), swh, Vatt, and sigh values for the test area. Statistical analysis in the form of autocorrelation, crosscorellation, correlation coefficients, and best fit lines to scatter plots were performed and calculated for the data. Correlation was calculated following Bendat and Pierot.[15] Correlation coefficient was calculated by a MATLAB routine. Specifically, we looked at σ^0 versus SWH, ionocor, sigh, Vatt, and wind speed.

Doug Vandemark supplied a graph of TOGA-TAO buoy[16] wind speed data that was taken when TOPEX passed within one mile nadir from the buoy within one hour of the time the data was uploaded from the buoy and a σ^0 over 16 dB was recorded.[17] This provided a nearly in situ measurement of wind speed. However, only 69 times since the buoy array was deployed have these conditions been met.

RESULTS

One SAR image correlated to a bloom was found (see the Web address listed in reference 12). This is an image of oil production off the coast of India, centered at 19.25 N and 71.35 E. TOPEX headed southbound over the region, crossing the top half of the picture from top left to middle right. The σ^0 is 14 dB at the top of the image and increases to 16 dB at the bottom.

A maximum in the autocorrelation function appearing to the right of the origin would indicate some periodic response in the spikes, whether temporal or spatial. All the autocorrelations generated showed no maximum.

Crosscorrelation between wind speed and σ^0 was plotted. A negative correlation was seen, which means high values of σ^0 occur at low wind speeds. This type of analysis for C band compared with K band showed the same spikes at the same times and places for the two bands. The only difference was the expected one of amplitude.

Several factors limited the amount of data analyzed. A few of the tracks started at the equator, headed north to 20 degrees, then wrapped around again from the south and finished at the equator. This created discontinuities in σ^0 and wind speed. About one tenth of the data tracks analyzed were for times where the ECMWF forecast changed days. This also led to discontinuity. An error in the program which downloaded wind vectors limited us to five good cycles of data, or five groups of ten days, each spread four to five months apart. Five cycles of ten tracks over the open ocean (north to south) were used, giving a data set of fifty records of wind vs σ^0. The same tracks were used for σ^0 vs the other types of data with all cycles available. Crosscorrelation was variable over the data set analyzed. Four examples of positive correlation (out of 50) were also found.

Scatterplots of wind vs σ^0 were made for each track. Correlation coefficient and a best fit line was also calculated for each track and the entire data set. Seventy-five percent of all spikes occurred at wind speeds below 5 m/s. The average values were calculated from the average of each track over the 5 useful cycles, where each average value was the mean at a certain geographical location. The significance (using the -0.356 correlation coefficient of average values) is 67.3%.[15] The significance of the slightly lower value of correlation coefficient ($\rho = -0.2421$) calculated from the overall data set is 91.9%. Out of 30,717 individual 1-sec averaged values analyzed, 2,229 had $\sigma^0 > 16$ dB, or 7.26%.

Scatterplots of swh vs σ^0 showed the expected inverse relationship. High values of σ^0 seemed to occur at low swh. Above about 4 m, spikes aren't present. Plotting the ionospheric correction (which varies from night to day) vs σ^0 showed no evidence of a correlation. Spikes did not produce corresponding anomalies in ionocor. The best fit line to σ^0 vs sigh shows an increasing value and thus higher standard deviation of height values as σ^0 increases.

Doug Vandemark at Wallops found 69 instances where TOPEX passed over a TAO buoy[17] within an hour of recording a σ^0 greater than 16 dB. The starting geographical distribution of the TAO buoy array can be found at the WWW address cited in reference 16. The wind speed for each TOPEX passover that included a σ^0 spike was never above 5 m/s.

CONCLUSIONS

From these results we can draw certain conclusions. We have a good match between a SAR image of man-made oil slicks and a spike in σ^0. This confirms the initial suspicions that spikes are caused by lack of surface roughness. More effort could be made to develop SAR images of surface slicks and match a shipboard study to the altimeter's over flight. An investigation of the ocean's air-water boundary layer could also shed more light on this phenomenon.

The autocorrelation showed no periodic characteristics either temporally or spatially. Spikes present during one pass have no effect on the following pass over the same area. This implies spikes are on a temporal scale that is shorter than one cycle, which is ten days.

Spikes look the same in both C-band and K-band. Both radar bands react to the phenomenon in virtually the same way. This is supported by the fact that the ionospheric correction values studied were unaffected by spikes.

The crosscorrelation between wind speed and σ^0 showed a net negative correlation as expected. However, a few tracks also exhibited positive correlation. The correlation coefficient between predicted wind speed and σ^0 was not very high. However, the correlation was shown to be statistically significant. We can be reasonably certain of the correlation between spikes and low winds. We must also keep in mind ECMWF winds are 12 hour averages interpolated onto the tracks from a 2.5 by 2.5 degree grid. This means we do not have the exact wind speed at the time and place Topex took the data. This level of accuracy is still meaningful. Over 75% of the spikes occurred at wind speeds of less than 5 m/s. It is likely that most of the other fourth can be chalked up to the error due to not having in situ measurements of wind speed. The best fit curve to the data was similar to the algorithm shown in Chelton & McCabe.[5]

The TAO buoy data shows spikes occur in winds under 5m/s. This method of in situ measurement showed no spikes over 5m/s. Both the predicted wind speed and the actual wind speed from the buoy does not show a link between wind speed and spike strength in dB. Forsooth, the amplitude of the spikes seems to be random. Perhaps amplitude is related to surface area of the slick or calm encountered.

The spikes cause higher than normal values of sigh. A linear relation between σ^0 amplitude and sigma height value was seen. This means that the higher the σ^0 the higher is the noise or error in the value derived for sea surface height. Current editing guidelines issued by the OSB say not to use data points for which the attitude marker is higher than 0.12 degrees. In the study region, this guideline eliminated most of the spikes > 16 dB. Using this guideline, only one percent of spikes over 16 dB remain in the data. However, 6% of spikes over 13.5 dB remain. Due to a counting loop error the actual data for these percentages is not precise. We can safely say editing rids the data of the very high amplitude spikes, yet a small part of the data still has σ^0 values larger than normal. Topex users should decide if this is significant to their research.

Cyberprint:
Creating Alternative Medical Visualization Tools Using Architectural Metaphors

Jim Agutter

Graduate School of Architecture
University of Utah
Art & Architecture Building
Salt Lake City, UT 84112

Faculty Advisor:

Dr. Julio Bermudez

The *cyber* PRINT project focuses on the need for medical visualization tools that aid doctors in the quick assessment and accurate monitoring of physiological conditions. Previous attempts at designing effective, real time, visualization devices have been hindered by poor graphic metaphors, and lack of design considerations. This design work helps to show associations of bodily functions by using traditional architectural representation methods and the metaphor of a building. The design ultimately becomes a depiction of an individual's physiological data in real time inside the digital space.

BACKGROUND

Humans are largely visual creatures. Throughout time humans have used pictures to communicate difficult concepts quickly and effectively. These pictures, like the ancient pictographs found in the Lascoux caves, help us make inferences that lead to better and quicker understanding of the message behind the picture. Research connected to thinking, imagination, intelligence, ideation, learning and other complex mental processes, shows that visualization plays a sophisticated and essential role in helping humans manipulate and understand information (Arnheim 1969, Bronowski 1978). In fact, our ability to use imagery has led to some of the most important technological, cultural and conceptual innovations in the history of humankind (Klima 1985). McCormick *et al.* stated in a report to the National Science Foundation ("Visualization in Scientific Computing") that there is so much information being produced today that all the scientists can do is archive it until a future date. This report postulates that interactive graphic displays are the best available solution in managing all this information due to their ability to convey large amounts of information in a simple and understandable way.

It is in the electronically sustained virtual environment of computers where the scientific visualization of complex data can finally take place and grow. Digital space can be seen as a database, that is, an information environment organized in a logical manner so that data is easily depicted, accessed, navigated, modified, stored, and retrieved. However, how this data is organized and modeled is up to the designers imagination. Data visualization needs not follow any particular course (i.e., literal, cultural, etc.) of representation, it may be modeled in an infinite number of ways. The only constraints are located in the bias of the human interface and the hardware/software capabilities. Given these instrumental constraints and the malleability of the digital canvas, decisions about what information should be deleted, highlighted, contextualized, or represented become very important. Medical visualization design should be the qualitative filtering and depiction of information towards achieving a clear end.

Most scientists whom develop these displays do not have the design background that would allow them to easily communicate large amounts of abstract data to different disciplines. Architecture bridges this gap, through it's millennia old design expertise. Architecture is well versed in the design and planning of multidimensional environments supporting human activities, as well as the representation, simulation and communication of diverse types of information. In addition, it deals with the spatial organization and resolution of complex information requirements and it addresses the human body in its multiple dimensions (scale, space, tectonics, etc.). There is a natural relationship between digital space and architecture that can be put to direct use in visualization design. Marcos Novak points out in his article "TransTerraFirma"

> *"To the extent that this development (i.e., the creation of virtual environments) inverts the present relationship of human to information, placing human within the information space, it is an architectural problem: but beyond this, cyberspace has an architecture of its own an, furthermore, can contain architecture.*

BEST COPY AVAILABLE

> *To repeat: cyberspace is architecture; cyberspace has an architecture; and cyberspace contains architecture"*

In other words, there is a natural relationship between digital space and architecture that could be put to use in visualization design.

DESIGN CONSIDERATIONS

Much of the work in the medical visualization field falls into one of two camps: (1) imaging (e.g., X-rays, CAT scans, etc.) and (2) interactive modeling of the body. These technologies are effective at displaying vast amounts of information but they are still confined to purely representational images rather than displaying a much more abstract depiction. This current paradigm stresses that the images are basically mappings of specific data on a computer modeled representation of the human body or head in a static way. Very little work has been done in the investigation of temporal depictions of physiology. The work that has been done has been carried out by the individuals who investigate the data; the scientists. However, scientists have the technical skills for implementation, yet they are trained in quantitative rather than qualitative methods, analytical rather than integrative processes.

The *Cyber* PRINT project goal is to create a coordinated and interactive hyper-representation that articulates physiological data in real time and in a format that is easily and quickly understood. The *Cyber* PRINT name comes from the fact that each individuals physiological data is unique to that individual much like a fingerprint, and that this information is contained within the digital environment. Ultimately, the *Cyber* PRINT would obtain its raw data from existing medical equipment that measures human physiological signs using non-invasive techniques. These include electrodes that measure heart rate, and a respirator device that measures breathing rate, volume and gas content in each breath. Currently, the information that is displayed in the new representation is obtained from a body simulator that mimics physiological responses based on an anesthesiologist's input. The current phase of the project is the development of an effective design that transmits the data in a clear and concise way

One of the first issues to be dealt with in the development of a new, real time, physiological representation, is to see how the integration of previously displayed distinct data can be achieved. Physiological activities within the body are all connected. When air is inhaled into the lungs there is pressure exerted on the heart by the lungs because of its close proximity. Due to this pressure, the volume of blood pumped by the heart changes with each beat. Understanding this type of interrelationship of bodily functions many problems during surgery can be brought about by another problem. For instance, when a patient experiences rapid blood loss the stroke volume of the heart decreases dramatically and the respiratory and heart rate rise as the body try to compensate for hypovolemia. When the interrelationship of physiological states is not adequately displayed, as in the current monitors, the physicians response time in identifying problems is much slower . (Figure 1). While this is the norm in the medical profession, recent studies have suggested that integrated graphic displays can reduce detection times of significant events(i.e. hypertension, rapid blood loss, etc.). Professor Dwayne Westenskow et al. at the University of Utah Department of Anesthesiology showed that using graphic integration with shapes and colors versus traditional wave and number based representations can dramatically reduce detection time.

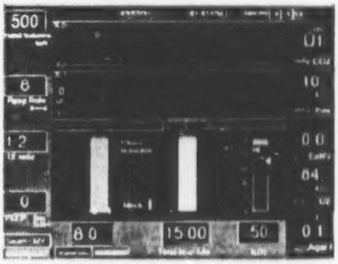

Figure 1: Standard for graphic displays used by anesthesiologists

In addition to its failure to properly show interrelationships between physiological data, it is difficult to view a history of the data in the current displays. While the historical information can be accessed via another screen that is separate from the current state screen it is not an adequate way to monitor trends as they occur. Therefore, a meaningful way to track history must be developed.

By providing auditory cues the current displays provide notification when something has gone wrong with the patient. However they lack pertinent visual cues to communicate problematic situations to the physician. This situation can be corrected by integrating informative colors and meaningful thresholds within the display. For instance, normal ranges can be displayed via a set of regulating lines and monotone colors. When the output transgresses these normal conditions vivid colors can be shown which would aid the physician to make a rapid assessment.

ARCHITECTURE AS METAPHOR

By integrating different variables such as heart rate and stroke volume (cardiac output * heart rate) and incorporating time, a 3-dimensional object can be constructed that displays this information (Figure 2). As time progresses the box is built with the thresholds of the current state rectangle making their mark which produce a 3-dimensional wave form. After the 3 minute mark the information would be collapsed into blocks of time. These blocks would display information from the 5 minute, 10 minute, and 15 minute mark. This 3-dimensional object can be viewed as an architectural construction much like a building. The building begins to have two components; one is the roof and the other is the wall. Both these components of the building protect the inside from the out but more importantly, the walls and roof help create individual spaces yet retain a connection to the whole construction with a tectonic or language of their own. This connection of disparate elements in buildings is intuitive for all people.

This form is conveyed through a series of standard architectural drawings such as plans, sections, oblique and axonometric views and elevations. When the physician wishes to obtain more information, such as a stroke volume wave-form, they can click on the appropriate side and an elevation view is brought up (Figure 3) This dual type of display can help bridge the gap between the new representation and the more traditional wave form that a physician may be more comfortable seeing.

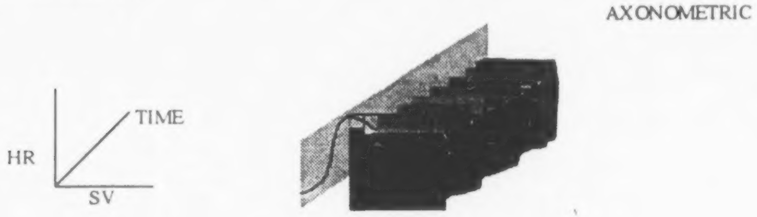

Figure 2: 3-dimensional architectural construction

By understanding simple physical principles it is known that in a gravitational environment, roofs cannot go unsupported. Something such as walls or another device must provide the support. This simple concept can aid in the communication of significant physiological events in our display. If, for instance, the wall becomes significantly detached from the roof a physician can easily tell that there is a problem with the stroke volume of the patient. Whereas with the old wave form representation the doctor must interpret what they are seeing which resulted in much slower recognition times (Westenskow).

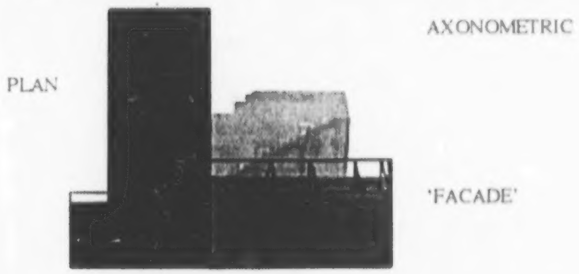

Figure 3: 3-dimensional construction with elevation views

For the physician to gain perspective on what is happening with the patient normal values must be displayed through a series of regulating lines. These lines are applied to the 'facade' of the building which displays the current condition of the patient. When the patient's physiological responses are within the normal values the front rectangle is contained in the regulating lines (see

Figure 2). If, perhaps, the heart rate is too high or low the front facade is either above or below the regulating lines. An additional visual cue can be added to help the physician in quickly monitoring changing conditions. When the current condition rectangle transgresses the boundaries, a brighter hue red can be displayed showing the degree of transgression.

To connect the physiological data even more a wall was placed to the left side of the construction (see Figure 1). On the wall would be displayed current drug content in the body and the time frame in which this would wear off. By directly associating the time frame of the drug content with the time frame of the heart rate and stroke volume a physician can directly see how the administered drugs are effecting physiological responses. These associations can be used as a powerful teaching device in training anesthesiology students.

CONCLUSION AND FUTURE WORK

The models that have been presented were developed as a schematic design on a Macintosh computer without regard to actual physiological data. This design is currently being transferred over to an IBM workstation where actual physiological data is being taken from the Body Simulator and converted into a digital representation. While the findings and investigation of the design have been very promising there is still an ongoing investigation involving different ways of representing the information. Currently a more organic design is being developed using spheres and brighter colors.

We live in a digital era. All areas of our lives have been touched in some way by computers. In this age of computers technology is advancing at a breakneck pace. With this advancement of technology comes increased amounts of information that must be dealt with. It is apparent that the way to deal with this information overload is to represent it in a pictorial way that allows for successful and quick communication. As the digital environment becomes more malleable through software and hardware improvements the way in which we display information becomes more of a question. The future of digital representation does not need to have its roots firmly planted in the past. It is up to individuals with differing backgrounds and talents to add to the knowledge base of information representation.

ACKNOWLEDGMENTS

The author would like to thank Dr. Julio Bermudez for his support and undying enthusiasm. Graduate School of Architecture Dean, Bill Miller for his support of this research. In addition, a hearty thanks to Dr. Dwanye Westenskow for his help with the design and expertise in the medical field.

Professor Rebecca Fish Ewan

ABSTRACT

This paper will discuss alternatives to typical residential building materials. Materials used in typical residential buildings are often mass-produced and shipped to the construction site. The environmental cost for shipping and producing these materials is enormous, and limits the diversity and design of the buildings. In the past, buildings were constructed from locally available materials and only limited by the availability of those materials. This paper will compare the use of historic building materials and present day materials, including a case study of planning and design of an education center and family residence in Canelo, Arizona. The paper will address the use of alternative architectural materials in this site and how to keep the site as a family residence, while maintaining it as a successful learning center. The site is in southeastern Arizona on a forty-acre plot of land in the basin and range area near the Huachuca Mountains. The owners run a nonprofit organization from this site and present seminars and workshops on the use of alternative buildings materials, such as straw bale, prickly pear cactus, and bamboo. Currently the site has no formal orchestration in locating new buildings, and an overall master plan needs to be developed. Also, there is no formal educational space. This paper introduces a master plan for the property and a design for a formal education space, emphasizing the use of locally available, alternative building materials.

INTRODUCTION

Sim Van Der Ryn and Stuart Cowan in Ecological Design, state " by working with living processes, we respect the need of all species while meeting our own. Engaging in processes that regenerate rather than deplete, we become more alive" (1996, p. 102). This quotation embodies the spirit of a family residence and education center in Canelo, Arizona. Owners of this forty-acre plot of land present workshops on alternative construction materials and their use on the site. Using alternative construction materials is not about creating new revolutionary materials, it is about revisiting the past and applying it to the present. The Canelo Project, a non-profit organization also apply historic construction materials to their site, while creating a sustainable residence for the owners and educating others about the process. This paper will discuss historic building materials and methods and compare the sustainability of their design to that of modern construction materials. Also, there will be discussion of the materials available on site and their applications with these historic methods. The site has no formal orchestration in locating new buildings and the family residence also serves as the educational center. Because of this, an overall master plan needs to be developed. To conclude this paper, this mater plan will be presented, which will include an application of historic construction materials to the outdoor educational center.

HISTORIC CONSTRUCTION MATERIALS

The owners of the site are not breaking new ground with their use of alternative construction materials. The materials and methods taught here have been used for centuries. They teach a method that predominately uses straw bales as the construction material.

Other methods that can be used in construction for this site include adobe brick construction, roof thatching and a system of wattle and daub wall construction. They do, although less frequently offer workshops on these other materials and methods.

Historically, straw has been used as a construction material for nearly forty thousand years (Bryce, no date). Hunting and gathering tribes of Africa used straw to build their homes and adobe bricks mixed with straw have been found in Jericho dating back to 8300 B.C. (Bryce, nd). Straw bale construction became mainstream in the plain states of North America in the late 1800's. Homesteaders in Nebraska started using straw bale for numerous buildings, including homes, farm buildings, churches, schools, offices and grocery stores (U.S.D.O.E. 1995), because a decent supply of wood was not available.

Adobe already existed on the site when the owners purchased this land; the existing residence was made using this construction method. This method can be done in numerous ways, anything from pouring layers of mud (a clay and sand mixture) on top of one another until a wall is formed or sun drying bricks of the same materials to build that wall. It is also used to weatherproof walls made from straw bales and wattle and daub. This method has been discovered in numerous Neolithic sites around the world, including Anatolia and Crete (Garrison, 1979). Adobe is still used widely as a construction method in Mexico and the southwestern United States.

Roofs made of thatch have been used around the world for many centuries (Brunskill, 1971). Thatch has been discovered in many climates and many countries ranging from the West Indies to Africa to England (Brunskill, 1971). Although it has not been widely practiced in the United States, many countries still construct roof structures in this manner. In England it has been elevated to an art form (Yarwood, 1963), it can only be learned by an apprenticeship under a trained craftsman. This is a method that owners of this site have only recently been experimenting with, using bear grass from the site.

Wattle and daub, possibly the most obscure methods mentioned, is a system of interweaving tree branches around posts, called staves and filling the cracks with an adobe mixture (Brunskill, 1971). The history of wattle and daub is comparatively short. This method was mainly practiced in England from the Roman occupation (from about 52 B.C.) to the twelfth century (Brunskill, 1971). As construction methods became more advanced wattle and daub became used less due to the lack of insulation (Brunskill, 1971).

In comparing the sustainability of historic methods and materials, appropriate to the southwest region, to their modern counterparts one must first define sustainable design for this site. For this site, sustainable design means using the locally available materials and creating minimal impact on the site. Included in this is the environmental cost, the theory of computing the costs to the environment, and impacts on the environment (Van Der Ryn and Cowan, 1996).

Currently in Arizona, housing is framed with wood, which is usually shipped a great distance from a wood mill. The tractor-trailers shipping wood to the housing site have a very high environmental cost, because they contribute to air pollution (Pijawka, 1995). After the framing is complete the walls are filled with a polystyrene insulation and finished with a gypsum wallboard, neither of which are contributing to, "processes that regenerate rather than deplete" (Van Der Ryn and Cowan, 1996). For Arizona, block construction is a typical method to finish the exterior of the house. The method used to make these blocks is far from an environmentally friendly action. For example, just the firing of the blocks releases a large amount of pollutants into the air. Other materials in the construction process are just as environmentally unfriendly. For example, outgassing from various materials, including roof tiles, paints and pavement for the driveway contribute to environmental degradation (Van Der Ryn and Cowan, 1996).

In contrast, the historic materials and building methods described above are considerably more sustainable for this site. Straw bales can be made from a variety of different plants, including barley, buffalo grass, native meadow hay, rye and oats (Bryce, nd). Straw bale utilizes the part of the plant stalk that is normally burned or plowed under by the farmer; over 200 million tons are burned in the United Sates every year (Bryce, nd). Although these straw bales are shipped to the site, the environmental cost of shipping and recycling the straw outweighs the environmental cost of milling the wood and shipping to the site. Adobe, whether it is to finish a wall or build a wall, is an extremely durable material and an extremely sustainable material, when compared to stucco finishes, gypsum wallboards, and block construction. The thatching of a roof and wattle and daub wall construction, using the environmental cost theory, greatly outweigh any modern method. Both methods use parts of plants that are normally thrown away, these methods are much less damaging to the environment. Even when considering the insulation of modern buildings, these alternative materials, with exception of wattle and daub, provide more insulation. For example, a modern house has a median R-value (the value given for insulation) of 19, a straw bale house with an adobe finish has an R-value of 50 (Bryce, nd).

CANELO PROJECT NATURAL RESOURCES

Canelo, Arizona is located in southeastern corner of the state near the Huachuca Mountains; sitting in the foothills called appropriately, the Canelo Hills. Specifically, the forty-acre site can be divided into three areas: Plains, Washes and Slopes. Turkey Creek, which is filled with water about eight months of the year, bisects the property. Geologically, the site is made of rock and soils from the Paleozoic Era, approximately 570 million years old. Soils in this site are a mixture of gravely clay loam and sandy clay loam. These very fertile soils are excellent for farming, and according to Roadside Geology of Arizona, "support grass-rich, non desert type of forage, making for ideal ranch country" (1983, p. 118).

Vegetation in this area is diverse, and can be correlated to the three landforms mentioned before, the slopes, washes and plains. The slopes, where the most plant diversity occurs, include various oak trees, agave, juniper, mesquite trees, and prickly pear cactus. Tall cottonwood trees lining the banks of Turkey Creek most easily identify the wash area. Bear grass, along with other grasses are plentiful in this area. Finally, the plains, which consist of about one fourth of the area of the site, contain yucca plants, bear grass, and blue gamma grass.

Given the natural resources on this site, the materials available for building are numerous. Rocks from the hills and creek bed can be used in paving roads, walkways and trails. Soils are fertile enough to grow wheat or a variety of other plants useful for food and building materials. Soils are rich enough in clay and sand to make an excellent adobe brick or adobe weatherproofing material. Cottonwoods and juniper trees can be trimmed back enough for ample firewood for the family and still frame structures without harming the trees. Their branches are also flexible enough to use in wattle and daub construction. Agave plants and prickly pear cactus, when fermented can be used as a finish for walls and floors. Even the bear grass is excellent for the thatching of roofs.

MASTER PLAN AND EDUCATION CENTER DESIGN

In developing the master plan three questions were addressed: How to separate the family residence from the main educational center; How to alleviate the need for more storage space for construction materials for the family; How to create enough housing to accommodate long term and short term guests.

The master plan has been divided into five important zones, each important to the organization of the site (figure 1). The first zone (number one on master plan) is where the new family residence is to be built. This site works the best because it is relatively flat ground, offers the owners a good view of their property and is removed enough from the education area to give the family privacy. Ultimately, a straw bale house can be built on this site with minimal impact to the site. The second zone is used for storage; parking and a new bridge to the new home would be placed here. There is a need for a garage; the family has two family vehicles, an earthmover, and a dump truck. This garage can be made large enough to include storage. This structure is perfect for the wattle and daub construction method, because a highly insulated building is not needed. Zone three is the most flat land in the site; it would be excellent for any crops the family would like to grow, or a possible expansion of the small apple orchard. Some guests prefer to tent camp when staying for the workshop and this site is the best site that is readily accessible to the educational center. The fourth zone is the site for the educational center, which will be explained in detail in the next section. Finally, the fifth zone is for wind power production and residential expansion. The wind is predominately southeastern majority of the year. With the addition of wind turbines the site could eventually free itself from the local power grid. This area is also excellent for residential buildings and one currently exists here. With the addition of residential buildings to the educational center, expansion is not going to be immediately necessary.

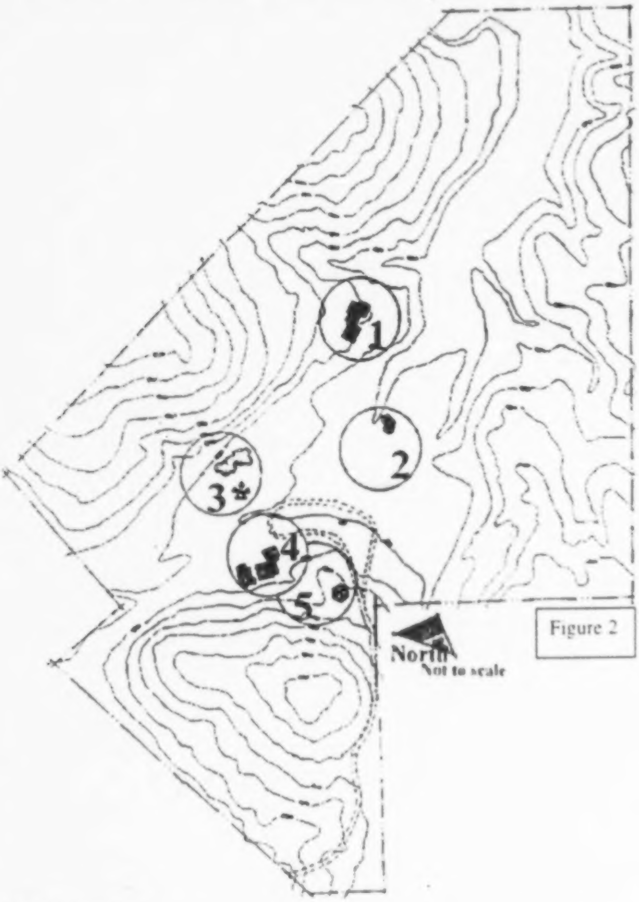

Figure 2

The site design for the education center must meet many needs (figure 2). This area must give the owners ample room to hold their workshops. These workshops usually consist of 15-20 people attending over a long weekend. It must be able to house the people that attend those workshops and the people that stay for extended periods. People also stay at the residence for a few months to research the methods taught here and needed longer-term housing. The family residence will become dormitory style housing. The guesthouse already serves as a dormitory, sleeping about eight to ten people. The family residence, after the new house for the family is built, will sleep about ten to twelve people. The front of the main house will be made into amphitheater seating for the presentation of lectures and slides. On the bottom level of the seating is a fire pit for guest to gather around; the temperature at night, even in the summer can get quite chilly. A path paved with river rock connects the three long-term residences; they can also serve as couple housing for the weekend workshops. A storage building has been put into this area. This solves both a long and short term need for storage. With the amount of materials that the owners require for the workshops this building is necessary. All of these buildings serve a dual purpose; they house the guests at the workshops and demonstrate of the construction methods and materials being taught at the Canelo Project. In the center of the courtyard the water feature completes the gathering area for the guests.

This site design and master plan will address the three main concerns. The family is separated from the educational center, which gives them some privacy. Storage buildings have been placed around the site, so they are accessible and convenient. The educational center has been enlarged and formalized, which increases the housing on site and demonstrates the application of the alternative materials and methods.

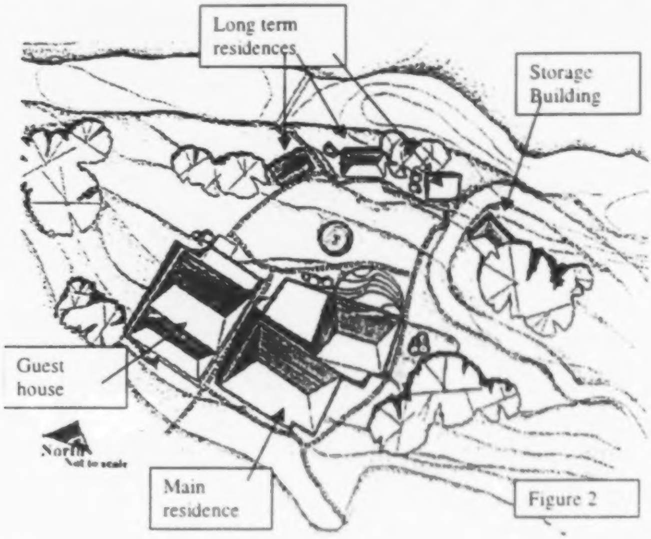

Figure 2

CONCLUSION

These historic methods and materials are what the site requires to have a sustainable design. The application of these methods and materials in the site shows that sustainability in a family residence is possible. Historic materials are a good way of revisiting the past, and finding a sustainable design and applying it to the present. It has been shown these historic methods can be applied on a small scale to a rural area. As for the next step, this sustainable designing needs to be applied on a larger scale. Currently, these methods and materials have been used sparingly in an urban environment. Investigating the application of these methods to a larger urban fabric must start on a grassroots level. Much like the operators of the Canelo Project, they educate about these historic methods hoping to create new paths in the future. Because as Rob Krier stated in his book Urban Space, "proper appreciation of our historic heritage will filter the experience of the past to the advantage of the planning the future" (1979).

An Analysis of Ancient Maya Obsidian Artifacts From Belize

Rissa M. Trachman

Department of Anthropology
University of Texas at Austin
Austin, Texas 78712-1086

Faculty Advisor

Fred Valdez, Jr

Recent excavations in northwestern Belize, Central America, have produced numerous obsidian blades and tools. The various artifact forms have been analyzed according to morphological characteristics and use-wear patterns. The latter fall into seven significant categories and were used to determine possible function(s) of the obsidian in ancient times. These were then correlated with contextual data for determining activity areas at excavated sites.

INTRODUCTION AND BACKGROUND

The Programme for Belize (PfB) Archaeological Project is a long term research effort in northwestern Belize aimed at identifying and recording archaeological remains of the ancient Maya in the Rio Bravo Conservation and Management area (Figure 1). The 1996 field season produced an obsidian collection of 46 artifacts excavated from four sites: Guijarral, Dos Hombres, My Lady, and Ma'ax Na. The collection of 46 obsidian specimens used for this study are identified as obsidian blade fragments (45) and one is an obsidian flake.

Obsidian is a volcanic glass usually associated with central Mexico and southern Guatemala. Obsidian has long been an item of trade or exchange particularly into lowland regions where it does not naturally occur. In the Maya lowlands this natural glass is a prized item often found in special contexts including burials and offerings.

The major objectives of this analysis were to provide: 1) a descriptive morphological analysis, 2) a descriptive analysis of use-wear characteristics derived from macroscopic observations, 3) possible function(s) of the obsidian based on the morphology and use-wear patterns, and 4) a determination of possible activity areas based on distribution areas within the sites.

DESCRIPTION OF OBSIDIAN SAMPLE

All pieces of the collection were examined and categorized as to morphology (shape) and edge wear patterns. The analysis and categorization performed followed the patterns set out from earlier studies (e.g., Clark and Lee 1979, Hester 1975; Shafer 1969; Sheets 1972; Valdez 1986, 1989, 1994). This study used the term "edge-wear" and "use-wear" interchangeably. Seven categories of wear were established by Thomas R. Hester (1975) while he studied the obsidian industry of Beleh, Guatemala. These same use-wear classifications were later utilized by Fred Valdez (1986, 1994) for obsidian collections from El Salvador and Honduras. The use-wear types are listed in detail below. When possible the proximal pieces were categorized into platform type as well.

A total of 46 pieces were retrieved as follows per site: 34 from Guijarral, four each from Dos Hombres, My Lady, and Ma'ax Na. There are 21 proximal fragments, 22 medial fragments, and two distal fragments. An interesting observation can be made of the distribution of the proximal, medial, and distal pieces between the four sites. Within the smaller samples of the Dos Hombres, My Lady, and Ma'ax Na sites there are only two medial fragments, while in Guijarral 20 of the 34 fragments are medial. Caution about interpretations or what this means must be voiced due to the small sample size. More than 99% of the specimens are identified as prismatic blade fragments comprised of proximal, medial, and distal segments. One artifact is a lithic flake.

Prismatic blades have parallel edges with one or more medial ridges on the dorsal side. Prismatic blades are at least twice as long as they are wide and are removed from a specially prepared core (Hester 1975, Valdez 1994). Core platforms are usually prepared by chipping or abrading the surface (see Hester 1975; Shafer 1969; Sheets 1973). Platforms are generally categorized as single or simple facet platforms, multiple facet platforms, and natural platforms (Shafer 1969). Single or simple platforms are predominate in this sample. Four possible multiple facet platform types can be observed. Four platform types are undetectable and are considered for the purpose of this analysis crushed platforms.

RB18 (Guijarral). Of the 34 total fragments (74% of total collection) there are 11 proximal, 20 medial, and two distal fragments. The proximal fragments measure from 11.07 to 56.01 cm (length), 8.23 to 12.02 cm (width), and 2.22 to 3.58 cm (thickness). The above measurements and those that follow represent the maximum measurements per dimension. The medial fragments measure from 11.64 to 35.39 cm in length, 6.51 to 15.41 cm in width, and 1.92 to 3.78 cm in thickness. The distal fragments, of which there are only two in the entire collection, measure from 13.50 to 22.99 cm in length, 6.98 to 9.33 cm in width, and 1.61 to 2.06 cm in thickness. One of the longer proximal specimens can be articulated, but was not broken prehistorically. It measures 53.04 x 9.49 x 2.22 cm (length x width x thickness). Of the proximal fragments, six exhibit signs of single facet platforms, two exhibit pointed platforms, one exhibits a multiple facet platform, and two are crushed and therefore undetectable macroscopically.

RB2 (Dos Hombres). There are four fragments (8.6% of total collection) from this site and all are proximal fragments. The fragments measure from 14.81 to 34.59 cm (length), 8.35 to 14.49 cm (width), and 2.52 to 4.23 cm (thickness). Of these proximal pieces, two exhibit single facet platforms, and two are crushed and undetectable.

RB48 (My Lady). There are again four fragments (8.6% of total collection) from this site, three are proximal and one is medial. The proximal fragments measure 32.02 to 40.25 cm in length, 10.31 to 19.68 cm in width, and 3.45 to 6.72 cm in thickness. The medial piece measures 19.52 x 15.48 x 3.49 cm. Of the proximal pieces, one is a flake. It appears to have the same characteristics as a lipped flake as described by Shafer (1969). The flake has cortex remaining on the dorsal side and exhibits signs of a multiple facet platform. The remaining two proximal pieces have single facet platforms. One of the proximal fragments and the medial fragment appear to have come from the same blade. They can not be articulated, however because the proximal end of the medial fragment was intentionally modified prehistorically. The modified end has had minute flakes removed creating a beveled profile. The altered edge is on the dorsal side leaving a flat plane on the ventral surface (Figure 2). This type of modification is reminiscent of scraper type tools. Thus, this small blade may have functioned as a tool used in minute scraping or smoothing activities.

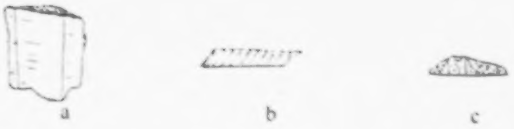

Figure 2. Various Perspectives of the Obsidian Blade Medial Fragment with End Modification, a) dorsal view, b) side view, c) direct view of modified edge.

RB49 (Ma'ax Na). Of the remaining four pieces in the collection (8.6%) three are proximal and one is medial. The proximal fragments measure 12.52 to 28.64 cm (length), 8.89 to 10.75 cm (width), and 2.50 to 2.63 cm (thickness). The medial piece is 12.69 x 12.89 x 2.47 cm. All three proximal pieces are of the single facet platform type.

WEAR PATTERN OBSERVATIONS

The use wear patterns for the collection fall into seven distinct categories (Figure 3) when using the same criteria as Hester (1975) and Valdez (1989,1994). Six blades from the collection exhibit two simultaneous types of wear and are counted separately below unless otherwise noted. The use-wear categories are as follows:

1) *Nicking* or miscellaneous wear is the predominant form of edge wear for the collection. Edge-wear in this category can result from use, depositional activity, or recent activity including excavation, transportation, and storage. Twenty-six specimens fall into this category and at least an additional four specimens exhibit this characteristic in addition to other edge-wear. The cause of the wear in this category is difficult to ascertain.
2) *Dorsal trimming* is considered observable wear on the dorsal side of the blade. This category of edge-wear may be the result of intense use. Edge modification of this type results from continued use in a specific motion for an extended exercise (time). Five specimens fall into this edge-wear category.
3) *Ventral trimming* is edge-wear to the ventral side of the blade. The edge modification referred to here may result from similar activity as mentioned for dorsal trimming. Only two of the blade fragments fall into this category.
4) *Fracturing* is seen as large areas or sections of the blade having been removed in one large piece or several small pieces. This type of wear can result from hard activity such as cutting bone or incising stone. Two blades can be included in this category of wear.
5) *Notching* or concave trimming is wear resulting in the removal of minute flakes from one or both lateral edges of the blade forming a clear notch. Six blades have edge-wear that is categorized as notching.
6) *Miscellaneous patterned wear* is represented by a segment or two of continuous minute flake removals. This type of wear is much more distinctive than nicking. Slicing and cutting activity result in this type of wear. Only one specimen from

BEST COPY AVAILABLE

this collection can be categorized with miscellaneous patterned wear.

7) *No wear* is the remaining category. Five blades can be categorized as such, and are blades that exhibit no edge modification.

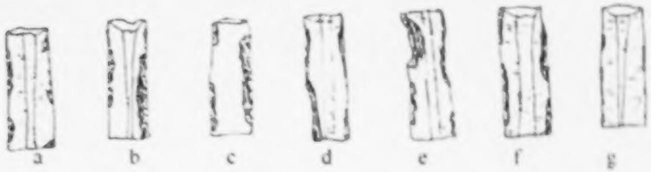

Figure 3. Stylized Examples of Use-Wear Categories. Modifications Depicted: a)Nicking, b) Dorsal Trimming, c) Ventral Trimming, d) Fracturing, e) Notching, f) Miscellaneous Patterned Wear, g) No Wear.

OVERVIEW AND INTERPRETATIONS OF THE PFB OBSIDIAN

In this paper 45 prismatic blades and one lipped flake were systematically analyzed for macroscopic edge-wear. At this time no microscopic use-wear analysis has been performed. The largest part of the collection came from Guijarral where extensive excavations took place. The small number of specimens from the other sites may reflect collection strategies that did not lend themselves to significant artifact recovery. Therefore statements of comparison between sites are not appropriate at the present.

Some type of use-wear is found on the majority of specimens indicating general use. However, fracturing, which might imply hard or extensive use, is minimally represented. Five blades showed no use-wear. These may have been curated for special placement (such as a cache) or for future use.

The Guijarral sample is best suited for comments about site activities. Most of the obsidian was collected from small residences away from the ceremonial center. These residences are believed to be the households of farmers in the area. The majority of the blades recovered from Guijarral are in the use-wear category of nicking. These blades were probably used in minor household activities such as simple (perhaps soft) cutting and slicing. Microscopic use-wear studies may reveal patterns of use such as sawing and slicing motions.

CONCLUSIONS

It is clear that obsidian was prized in this community where the raw material was not subjected to more difficult or hard tasks. In this way, the obsidian lasted longer.

As a general model the PfB sample is similar to other lowland Maya collections for obsidian form, mostly blades, and the number of blades in each use-wear category. It seems most likely that obsidian arrived or was traded into the region in blade form rather than as cores. It may be that the specialization of producing blades was most developed in highland areas near the obsidian sources.

Effects of Detention Time on Sedimentation Performance

Ben Ehrhart

Department of Agricultural and Biological Engineering
The Pennsylvania State University
239 Agricultural Engineering Building
University Park, PA 16802

Faculty Advisor: Dr. A. R. Jarrett

A full scale sedimentation basin was constructed with a total capacity of 1800 ft^3. Four experimental runs were conducted, each of which had identical 1630 ft^3 inflow hydrographs over a 100 minute period. Six hundred pounds of soil were added to each run in increments with the hydrograph. Two runs had detention times of six hours, and two runs had detention times of seven days. For each detention time, one run was conducted with a perforated riser as the principal spillway and the other with a skimmer. Both seven day runs resulted in considerably higher sediment retention efficiencies (98.5% for the skimmer and 97.1% for the perforated riser) than the six hour runs (92.9% for the skimmer and 84.0% for the perforated riser). For both detention times, the skimmer had a higher sediment retention efficiency than the perforated riser. The seven day skimmer resulted in a finer effluent particle size distribution throughout the dewatering than the other three spillways.

INTRODUCTION

Accelerated erosion resulting from human activities has long been recognized as a serious concern. Displacement of soil can cause reduced agricultural productivity, and sediment deposition can shorten the life of reservoirs. In addition, transport and deposition of soil is to blame for a plethora of environmental problems.

Eroded soil and runoff from non-point sources is a major transporter of nutrients. According to the USDA (1989), 80 percent of the total phosphorus and 73 percent of the kjeldahl nitrogen in U.S. streams is attributed to erosion. Phosphorus, the limiting nutrient in aquatic systems, can cause algae blooms which block sunlight penetration to deeper waters which ultimately depletes the dissolved oxygen necessary for aquatic life. Nitrogen can aid in oxygen depletion, and in addition, high nitrate (NO_3) concentrations can cause methemogobanemia, a potentially deadly condition to which infant mammals are susceptible.

There are also physical problems associated with erosion and sedimentation. Suspended sediment cause high turbidity which is unhealthy for aquatic organisms and a concern for public water supplies. Sediment deposition in streams, lakes, reservoirs, and estuaries smothers benthic organisms, interferes with fish spawning, and, as previously mentioned, prematurely fills reservoirs.

It is clear that soil erosion and sedimentation is a problem that merits serious consideration. Clark et al. (1985) estimated that soil erosion by water costs the United States $6.1 million annually. It is difficult to put a price tag on the environmental damage that is caused.

Best management practices on farms, construction sites, and other earth disturbance areas can prevent or reduce the detatchment and transport of soil particles, or on-site erosion. When on-site erosion does occur, however, measures must be taken to prevent the transport of this soil accross propety lines or into waterways. Sedimentation basins are commonly used in this role, and they have been proven effective in reducing off-site transport of sediment by runoff.

Sedimentation basins are impoundment structures designed to intercept runoff from storm events and dewater slowly to allow settling of suspended soil particles. These structures have been used extensively at mining sites as well as urban and construction areas. Although agriculture is responsible for the greatest percentage of the total sediment load in the United States (Goldman et al., 1986, Ward et al., 1979), use of sedimentation basins on farmland has been avoided in favor of on-site control practices.

OBJECTIVES

The objectives of this research were to evaluate the sediment retention capability of an 1800 ft^3, full scale sedimentation basin to determine:

1. The relationship between basin detention time and sediment retention efficiency,

2. The effect of basin detention time on effluent particle size distribution, and

3. The effects of basin detention time on effluent water quality as a result of using a perforated riser and a skimmer as principal spillways to control the effluent discharge rates and position within the water column from which the effluent was withdrawn.

BEST COPY AVAILABLE

FACILITIES AND PROCEDURES

Sedimentation Basin

An 1800 ft^3 sediment retention basin was designed and built at the Pennsylvania State University's Russel E. Larson Center at Rock Springs (see Figure 1). The basin length from inlet to outlet was 40 feet, and the bottom width at the lower end was 16 feet. The crest of the emergency spillway was at a depth of 3.5 feet.

Water was supplied to the basin from a permanent Pond, located directly upslope. Water was delivered from the permanent pond by gravitational flow through a six-inch PVC pipe. The flow rate was metered through an orifice plate by a differential manometer system and controlled by a gate valve housed in an instumentation pit (see Figure 1). A four-inch PVC pipe delivered water from the gate valve to an 18-inch double-walled polyethylene pipe. A large funnel in the top of the polyethylene pipe allowed soil to be injected into the water before it entered the basin. Water exited the basin through the principal spillway and the six-inch PVC barrel which discharged into a 0.8-foot HS-Flume. The effluent was then released into a nearby swale.

Data Collection

The outflow hydrograph was measured by a float in the stilling well of the flume. The depth of water in the flume was recorded by a Belfort 5-FW-1 portable liquid level recorder. This depth was converted to a flow rate using the flume calibration.

Water quality samples were collected automatically from the flume by an ISCO model 2900 sampler. One-liter samples were taken at pre-programmed intervals for sediment concentration and particle size analysis.

Experimental Runs

Four experimental runs were conducted consisting of all combinations of two principal spillways and two detention times (see Table 1).

Table 1. Description of Experimental Runs

Run	Detention Time	Spillway	Orifice / Hole Diameter
1	6 Hours	Skimmer	2.25 inches
2	6 Hours	Perforated Riser	0.906 inch
3	7 Days	Perforated Riser	0.156 inch
4	7 Days	Skimmer	0.400 inch

All four spillways were designed to dewater the basin in the appropriated amount of time. The perforated risers were designed based on the technique developed by Jarrett (1993) using the stage-storage relationship for the basin. Both perforated risers were constructed from four inch PVC pipe with a single column of holes at six-inch vertical intervals. The six hour riser had 0.906-inch holes, and the seven-day riser had 0.156-inch holes.

The other principal spillway used was a skimmer (figure 2), designed to withdraw effluent from the surface of the basin. In theory, the cleanest water should be present at the top of the water column. One skimmer with interchangeable orifice plates located at the top of the skimmer arm was used for both detention times. Orifice sizes, which were determined using the skimmer equation developed by Jarrett (1996), were 2.25 inches for the six-hour run and 0.4-inch for the seven-day run.

All four runs had identical inflow hydrographs and sedigraphs (Figure 3). Approximately 1630 ft^3 of water was metered into the basin for each run, which represented runoff from a two-year, 24-hour storm in State College, PA from a one-half acre watershed (1% slope, SCS-CN = 80). The inflow hydrograph took 100 minutes to enter the basin, with inflow rates adjusted every 2.5 minutes. Six hundred pounds of Hagerstown silt loam A-horizon soil were added through the soil injection funnel during each run before the water entered the basin. Buckets were used to measure the soil which was added in ten, ten-minute intervals to create the sedigraph shown in Figure 3.

Water quality samples were collected at ten minute intervals while the basin was being loaded. During dewatering, samples were taken at 30-minute intervals for the six-hour runs, and six-hour intervals for the seven-day runs.

Laboratory Analysis

Each effluent sample was analyzed for sediment concentration and particle size distribution. The one-liter samples were shaken and 125 mL was poured into smaller bottles for particle size analysis. The remaining sample was allowed to settle for 24 to 48 hours. Samples were then weighed, filtered, oven dried, and weighed again to determine mass of sediment, volume of water, and ultimately, sediment concentration. Sediment concentration of the influent pond water was also determined, but was found to be negligible.

Particle-size distributions were determined using a Shimadzu Laser Diffraction Particle Size Analyzer (SALD 1100). The particle size distribution of a composite soil sample of the soil used for injection was also determined.

RESULTS AND DISCUSSION

Hydrographs

Each of the four runs had a distinct outflow hydrograph. Figure 4 shows the outflow hydrographs for the six-hour spillways. The seven-day outflow hydrographs had the same general shape as the six-hour hydrographs. The perforated risers had a peak flow at the end of the 100 minute loading period, and the flow declined gradually through the duration of the run. Outflow rates from the skimmers also peaked at about 100 minutes, but because of the orifice control and nearly constant head, the peak was lower relative to the perforated riser, and flow rates only declined slightly throughout the dewatering period. Peak flows were 0.067 cfs for the six-hour skimmer, 0.119 cfs for the six-hour perforated riser, 0.0069 cfs for the seven-day perforated riser, and 0.0025 cfs for the seven-day skimmer. Detention times were slightly longer than six hours and seven days for the respective runs, but the discrepancies were negligible.

Sediment Loss

Sediment concentrations (Figure 5) for the six-hour runs peaked during the first 100 minutes, and fell sharply, remaining low for the remainder of the runs. The perforated riser had a peak concentration of almost 10 g/L, while the skimmer peaked at just over 4 g/L. After two hours, both risers maintained sediment concentrations below 1 g/L.

The seven-day runs showed a similar pattern (Figure 6), with the perforated riser peaking at 1.94 g/L and the skimmer peaking at 2.24 g/L. The sediment concentration from the skimmer dropped more dramatically following the peak than did the perforated riser, falling to 0.65 g/L in only ten minutes. After 20 hours, concentrations from both risers were less than 0.25 g/L. Surprisingly, the perforated riser maintained lower concentrations than the skimmer after this point.

The skimmer had a higher sediment retention efficiency for both detention times. The skimmer's higher sediment concentrations relative to the perforated riser throughout most of the seven day run did not result in a higher total sediment loss because the flow rate and the sediment concentration of the perforated riser was much higher than the skimmer prior to the 20-hour point in the run. Most of the sediment that was lost was lost before this time.

Retention efficiencies for both spillway designs were considerably higher for the seven-day runs. Soil loss ranged from 8.77 lbs. for the seven-day skimmer to 96.06 lbs. for the six-hour perforated riser. Those losses translate to retention efficiencies of 98.5% and 84.0% respectively (Table 2).

Table 2 Total Soil Loss and Sediment Retention Efficiency

Run	Total Soil Loss	Retention Efficiency
6 Hr Skimmer	42.44 lbs.	92.9%
6 Hr Perf. Riser	96.06 lbs.	84.0%
7 Day Skimmer	8.77 lbs.	98.5%
7 Day Perf. Riser	17.27 lbs.	97.1%

By extending the detention time by a factor of 28 (six hours to seven days), the sediment loss was decreased by a factor of 11 when the perforated riser was used. The same increase in detention time decreased sediment loss by only a factor of 2.5 when the skimmer was used. Althought the skimmer discharged less sediment at both detention times, the perforated riser showed a greater degree of improvement from the six-hour to the seven-day detention time.

Particle Size Analysis

Particle size distributions were determined for each sample. The perforated risers for both detention times had nearly identical distributions at each time shown, and the distributions varied very little throughout the runs. The six hour skimmer distribution was similar to that of the perforated risers at 25% duration, but at 50% duration the skimmer distribution shifted to the left indicating a lower percentage of larger particles. This trend was reversed, however, as the depth of water decreased and the skimmer approached the bottom of the basin. By the 95% duration point, the six hour skimmer particle size distribution had shifted to the right of the perforated riser distributions.

Throughout the entire run, the seven day skimmer particle size distribution was considerably finer that the other three treatments. The distribution also became finer as the run progressed. This was expected because the larger particles should settle faster than smaller particles according to Stoke's Law. Therefore, the particle size distribution in the basin, especially at the surface where the skimmer is located, should become finer with time.

Figure 7 illustrates percent soil loss with respect to particle sizes. There was a strong relationship between the particle size distribution of the soil entering the basin and the distribution in the effluent. This relationship was also seen by Millen and Jarrett (1996). The skimmer was more efficient in removing silt sized particles when compared to a perforated riser designed for the same dewatering time, but the difference was not as clear for clay sized particles. Detention time, however, had the greatest impact on soil retention for each particle size.

BEST COPY AVAILABLE

CONCLUSIONS

1a. Increased detention time improved sediment retention efficiency from 84.0% to 97.1% when perforated risers were used.

1b. Increased detention time improved sediment retention efficiency from 92.9% to 98.5% when skimmers were used.

2a. Increased detention time had no significant effect on particle size distributions when perforated risers were used.

2b. Increased detention time resulted in a finer particle size distribution when skimmers were used.

3. Skimmers had higher retention efficiencies than perforated risers for a given detention time.

4. Effluent particle size distribution was strongly related to influent particle size distribution regardless of principal spillway or detention time.

CHARACTERIZATION OF WASTE SITES IN GREATER NEWARK AREA USING GEOGRAPHIC INFORMATION SYSTEMS (GIS)

Jelena Balorda
Civil & Environmental Engineering Department
New Jersey Institute of Technology
Newark , NJ 07102
Faculty advisor: Dr. Sima Bagheri

The objective of this project was to identify and delineate existing potential hazardous waste sites and establish a buffer zone using the technology of GIS to protect both human and natural resources within the study site. The study site is the southeast portion of the Newark metropolitan area, a highly industrial area, potentially producing high levels of hazardous materials. The methodology consisted of interpretation of various geospatial data sets derived from different sources and their integration into a GIS to generate the database. The GIS contains information on characteristics and locations of waste sites and their impacts on environmentally sensitive areas (i.e. wetlands and surface water resources) and human resources. A buffer zone was established to assess the proximity and potential hazards of these sites to both human and natural resources. In conclusion, the technology of GIS can be used as a non-invasive and cost-effective tool in gaining detailed information on waste sites and their impacts on the ecosystem and human welfare.

INTRODUCTION AND CHARACTERISTICS OF THE STUDY SITE

The Newark Metropolitan area is a densely populated and highly industrial area. Various types of industry, currently active or inactive have produced and disposed of many potentially hazardous materials over the past decades. Many of the plants have closed their operations after the EPA has set stricter regulations, but their former locations have remained contaminated. Some of the contaminants found are various liquids and vapors designated as Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Hazardous Substances. Many of the substances present a potential threat to the public through direct contact and spillage or may cause fire and/or explosion through vapor emission (USEPA, 1993).

The objective of the project was twofold: 1) to identify and delineate these sites, and assess their location as well as their proximity to the residential and environmentally sensitive areas, and 2) to establish a buffer zone and rank them for better management of the existing and incoming industries as well as the preservation of Newark's natural resources.

The study site is located within the Newark Metropolitan area in Essex County, New Jersey (Figure 1). This area is densely populated and located adjacent to a highly industrial zone. The predominant industries in this zone produce chemicals, paints, oils, and lubricants. These plants have historically produced and stored various chemicals and hazardous wastes at levels dangerous to human health and environment.

Geologically the study area is a part of the Piedmont province and it's Triassic Lowlands (Widmer, 1964). The sedimentary rock is of the Brunswick and Stockton formations of the Newark Basin group. Locally, the Brunswick formation consists of red shale with interbedded sandstone. The Stockton formation consists of red micaceous sandstone with interbedded sandstone. Diabase Igneous rock has intruded into the sedimentary rocks. Glacial features of Wisconsin age (Pleistocene Epoch) represent the hummocky topography and consist of poorly sorted clay to boulder size material. The soft red shale of the Brunswick formation underlies the glacial deposits usually at depths greater than 15 feet. The thickness of the shale varies between six to eight thousand feet. The drainage is generally good, the depth to water table is estimated to be 6-10 feet (Engineering Soil Survey, 1951).

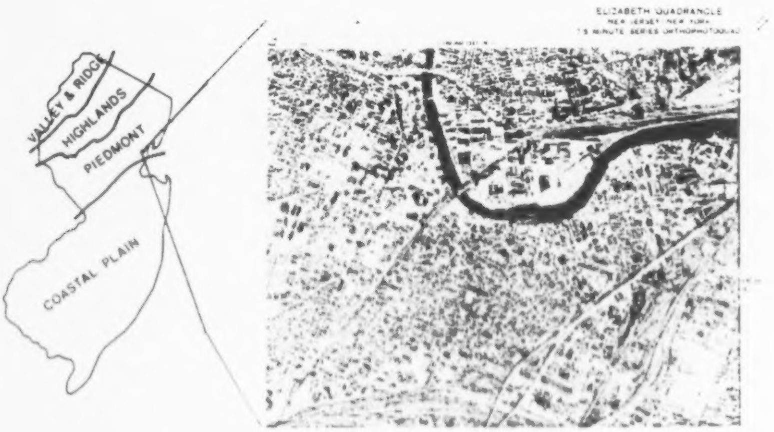

Figure 1. Portion of the Elizabeth Orthophoto Quadrangle Showing the Study Site.

RESEARCH MATERIALS AND DATABASE DEVELOPMENT

The characteristics of input data integrated into the GIS are listed in Table 1.

Table 1. Sources of Data integrated into the GIS.

Data Source	Scale	Type
USGS Elizabeth Quadrangle Orthophoto	1:24,000	analog
USGS Elizabeth Quadrangle Topographic Map 7.5 minutes series	1:24,000	analog
US Census Bureau Essex County, NJ Tiger 94	1:100,000	digital
USGS Digital Line Graph (DLG) hydrography and boundaries	1:24,000	digital

The descriptions of the input data are as follows: USGS DLG data files are digital representations of cartographic information, containing a full range of attribute codes (i.e. node, line and area identifier elements) and topological structuring (EROS web site, 1996). Topologically Integrated Geographic Encoding and Referencing (TIGER)'94 data files are various census and geographical data in digital format, developed by the U.S. Census to support their mapping needs starting with the Decennial Census of 1990 (U.S. Census web site, 1997).

Industrial Recovery Sites Act (ISRA) data layer was based on information introduced by the New Jersey Department of Environmental Protection. ISRA guarantees prospective buyers of commercial sites that these sites will be fully evaluated for contamination above and below ground. All contaminants are required to be identified and remediated by the seller (Bergen County web site, 1995). Currently the type of contamination present and the level of health risks to public and the environment are not yet determined. Many of the sites are abandoned chemical plants, landfills and junk yards covering large areas within the study site.

Integration of data into GIS was accomplished using ArcView, a GIS software developed by ESRI (ESRI, 1996). The Elizabeth quadrangle orthophoto was scanned to digital format and georeferenced to the Universal Transverse Mercator (UTM) projection system using ERDAS (ERDAS, 1995) image processing software. The digital orthophoto was then used as the base map. The USGS 7.5 minutes topographic quadrangle of Elizabeth was used as a reference map in order to verify the airphoto interpretation derived from the orthophoto. The TIGER'94 file data was reprojected to the UTM projection system using the PC-Arc/Info Data Automation Kit (ESRI, 1996). The Digital Line Graph (DLG) containing hydrography and boundary data used for delineation of wetlands, streams and canals were reformatted for input into GIS. All data sets were on the same projection, datum, ellipsoid and scale.

To achieve the objective of the project, human component (i.e. schools and hospitals) and environmentally sensitive component (i.e. parks and green areas) were delineated and identified using the standard symbols. In addition to the layers mentioned above, the ISRA layer was generated and input along with its attribute table, which contains information on the partial listing of abandoned ISRA sites. The method of identifying and delineating the individual ISRA site was largely based on the information found in TIGER'94 attribute table (containing street addresses). Data from Tables 2 and 3 shown here were linked together by means of a unique identifier--street addresses.

For the purpose of model development a buffer zone was established around the delineated waste sites/landfills. Proximity analysis was performed in order to assess the impacts of such sites on the human welfare (i.e. schools and hospitals) (Figure 2). The criteria used to rank the susceptibility of both human and natural resources are as follows:

1. 500 ft – unsatisfactory
2. 1000 ft – marginal
3. 2000 ft – satisfactory

Note: Based on the criteria set by NJDEP waste disposal sites should not be within 2000 ft of human and natural resources (NJDEP, 1984).

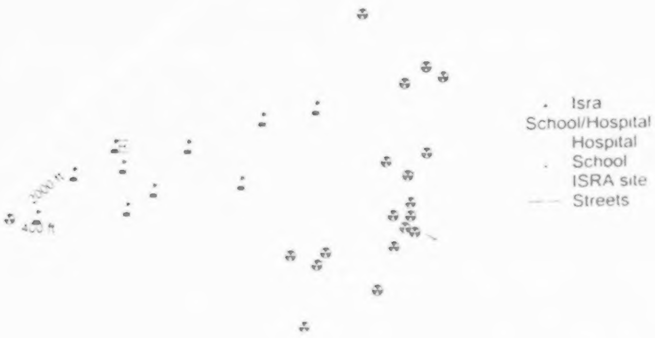

Figure 2. Location of Stored Waste Sites and Their Proximity to Schools and Hospitals.

CONCLUSION

The GIS developed in this study contains a variety of data and information useful for purposes of site assessment and planning, monitoring and management of waste sites and their impact on environmentally sensitive areas. It proves as an efficient and cost effective tool for planners, engineers, developers, and industry.

ACKNOWLEDGMENT

ELECTROCHEMICAL AC IMPEDANCE TECHNIQUE TO INVESTIGATE THE INHIBITION EFFICIENCY OF AN INHIBITOR FOR STEEL REBAR IN CONCRETE

Octavio Cervantes, Elaine Lopez & Rudolph Martinez

Department Civil and Manufacturing Engineering
California State University, Northridge
College of Engineering and Computer Science18111 Nordhoff St., Northridge, CA 91330

Faculty Advisor
Behzad Bavarian, Ph. D

The purpose of this investigation was to determine the effectiveness of an aromatic anodic inhibitor to the corrosion of rebar in concrete which will be referred to as INHIBITOR. The corrosion behavior of reinforced concrete was monitored for 28 days in solutions of NaCl and $FeCl_3$ utilizing the AC impedance technique. A number of variables were considered. These included the amount of concrete cover (1" or 2"), as well as the presence or absence of the inhibitor admixture. In addition, half of the samples contained holes to increase the rate of chloride diffusion to the rebar. Bode plots were generated to determine the effectiveness of the inhibitor as a corrosion inhibitor. Furthermore, the open circuit potential of all specimens was monitored as a function of time to examine the probability of specimen corrosion, this was done accordance with ASTM C876

INTRODUCTION

The corrosion of reinforcing rebar in concrete is a major problem affecting the integrity in of numerous structures [5,3]. Corrosion of steel rebar takes place in the presence of moisture, oxygen and chloride ions. These elements enter reinforced concrete through pores, capillaries and tiny cracks in the surface and attack the steel rebar [1]. Reinforced concrete may also be of exposed to chloride ions which exist in deicing salts and marine environments [5,3]. Moisture containing these chloride ions diffuses through the surface and comes in contact with the rebars[1]. In spite of concrete's characteristically high pH (10-13) chloride ions depassives the steel reinforcement [1,4]. As chloride ions penetrate, they form electrolytes within the concrete, increasing the formation of corrosion cells, thus creating rust (oxidation)[1]. As the oxidation continues, rust build up on the rebars causes them to expand many times their its original size[1]. This may cause the concrete to crack and spall, further exposing the rebars and leaving them open to additional corrosion[1].

An attempt to alleviate these corrosion problems, a chemical company has developed a new corrosion-inhibiting admixture inhibitor. The manufacturer claims that the inhibitor effectively reduces corrosion by depositing a protective layer that inhibits corrosion on imbedded steel and actually increases corrosion protection as the structure ages. Once the layer is formed it is claimed to remain, thus extending the service life of structures subjected to chloride attack.

EXPERIMENTAL PROCEDURE

A total of 48 reinforced concrete specimens were obtained. All specimens, with dimensions of 4"x4"x12", were prepared from pre-mixed concrete and were cured for 28 days. Half of the specimens had concrete cover of two inches, and half had one inch of cover. A 1/2 inch, grade 60, steel rebar was placed one inch from an Inconel 800 counter electrode in each specimen to complete and electrochemical cell with an external $Cu/CuSO_4$ reference electrode. Various specimens contained holes to increase the diffusion of chloride. In addition, a total of twenty-four concrete samples were prepared with the inhibitor to study the effectiveness in inhibiting corrosion of the steel rebar. The addition of the inhibitor was in accordance with the manufacturers' recommendations (1/2 gallon per cubic yard of concrete, or 2650 ppm).

Immersion and testing of the twenty-four specimens in 60,000 ppm NaCl solution began on February 1 of 1996. Beginning two weeks thereafter, simultaneous tests were conducted on the remaining twenty-four specimens submerged in a 400 ppm $FeCl_3$ solution. The concentration of the $FeCl_3$ solution was increased on day 47 from 400 ppm to 4000 ppm, since there was no indication of the occurrence of corrosion in either set of samples. On day 112, five of the specimens, which showed very low resistance polarization and open circuit potential were

BEST COPY AVAILABLE

sectioned to inspect for corrosion. Every rebar had a rim of corrosion product around it (rust formation). Testing duration was 28 weeks of immersion in NaCl and $FeCl_3$.

The following specimen identification was utilized throughout the study: a b c d where,

a = inches of concrete cover (1" or 2")
b = presence of holes on the specimen (indicated by "Y") or absence of holes on the specimen (indicated by "N")
c = presence of inhibitor x on the specimen (indicated by "Y") or absence of inhibitor x on the specimen (indicated by "N")
d = sample number (1 through 6)

DISCUSSION OF RESULTS

The data gathered in this investigation for the submerged concrete specimens in NaCl and $FeCl_3$ solutions were reduced to Bode plots and Potential vs. Time graphs. Bode plots generated through the use of AC impedance spectroscopy allow for conclusions to be drawn as to changes in the resistance polarization of the reinforcement in the concrete with respect to time of submersion in solution. This resistance polarization value or Rp is a measure of the steel's surface resistance to corrosion. The Bode plots contained in this report demonstrated clearly that with time the impedance of the rebar is decreasing and approaching the impedance of the solution in all case conditions.

Figure 1 consists of specimens with holes submerged in NaCl solution with one inch of concrete cover. This graph compares the effectiveness of the inhibitor admixture. A drop in impedance occurs in the specimens containing the admixture and the same holds true for those specimens which do not contain the admixture. Figure 2 consists of specimens without holes submerged in NaCl solutions with one inch of concrete cover. The same behavior occurred as a drop of impedance was illustrated in samples with and without the inhibitor admixture. Figure 3 correlates the probability of corrosion problems in accordance with ASTM C876. A drastic change occurred in specimen 1ny3 as its open circuit potential experienced a voltage drop from -0.241 V to -0.698 V after test day 108 indicating that depassivation of the rebar had occurred [3]. Figure 4 consists of specimens without holes submerged in $FeCl_3$ solution containing one inch of concrete cover. A drop of impedance was again significant in both cases regardless of the presence or absence of the inhibitor admixture. Figure 5 correlates the probability of specimen corrosion to an accompanied voltage drop. This figure indicates that there is a 90% probability of corrosion attack in both cases after day 90.

Figure 6 consists of specimens with holes submerged in NaCl solution containing two inches of concrete cover. A decrease of 50 times impedance occurred in the sample 2yy3 containing the inhibitor admixture from day 8 to day 183 and a decrease of 5.5 times its impedance occurred in the sample 2yn3 without the admixture from day 8 to 189. Figure 7 consists of specimens without holes submerged in NaCl also containing two inches of concrete cover. A drop of 5 times its impedance occurred from day 43 to 189 for the sample 2ny3 containing the admixture, while a decrease of 6 times its impedance occurred from day 35 to 189 for the sample 2nn3 without the admixture.

Figure 8 consists of specimens with holes submerged in $FeCl_3$ solution containing two inches of concrete cover. A decrease of 3.5 times its impedance from day 5 to 166 occurred in the sample 2yy5 with the admixture while a decrease of 2 times its impedance from day 30 to 166 occurred in the sample 2yn5 specimens.

CONCLUSIONS

AC electrochemical impedance spectroscopy indicated that INHIBITOR in ineffective as a corrosion inhibitor for steel rebar in concrete in a chloride containing environment. Thus the following conclusions were established:

1. Concrete specimens with one-inch of cover experienced a reduction in resistance polarization, Rp, (indicative of corrosion), regardless of the presence or absence of the inhibitor, after 70 days of immersion in NaCl.
2. Concrete specimens immersed in $FeCl_3$ showed reduction in Rp after 90 days.
3. Physical evidence of rebar corrosion was observed after 112 days of immersion within the one inch concrete cover samples.

4. Concrete specimens with a two inch cover experienced a significant reduction in resistance to polarization toward the latter end of the project (140 days) for both solutions. This slower rate of corrosion may be attributed to inward diffusion of chloride through the concrete.

ACKNOWLEDGMENTS

The investigators will like to thank the Metropolitan Water District of Sourthern California for their sponsorship of the project. To our advisors and principal investigations Dr. Behzad Bavarian and Dr. Roger DiJulio. Finally, to the Department of Civil and Manufacturing Engineering at California State University, Northridge for facilitating us with equipment and materials.

Research technology can offer any enterprise a competitive edge, but before employing a research result, structural engineers require evidence that it can reduce design time as well as construction costs. This paper illustrates design and analysis procedures for a new structural column, the concrete-filled steel tube (CFT), by developing prototype building frame configurations. Although prior research has demonstrated the improved strength and economy of individual CFTs over more common concrete or steel columns, this paper explores their behavior as a part of complete structural systems by integrating CFTs into building frames and pinpointing the aspects of CFT behavior fundamental to achieving efficient design. The composite CFT framing configurations included in the study vary in number of stories, number of bays, and bay spacing. The member sizes, patterns of deformation, and sequence of failure due to wind and seismic loading are examined for each CFT configuration and contrasted to the behavior of steel buildings. Several configurations produced efficient designs, exhibiting consistent, predictable response to both load types. These prototypes provide a basis for the practical design of CFT frames in the future.

INTRODUCTION

This research project examines the behavior of building frames consisting of steel wide-flange girders rigidly-connected to concrete-filled steel tube (CFT) columns. Although currently in limited use in practice, prior research has shown improved strength of CFTs over similarly-sized steel or reinforced concrete columns (Bridge and Webb, 1993). The perimeter location of the steel within the cross section provides optimal flexural strength and stiffness, and continuous confinement by the steel tube allows concrete to retain strength and deformation capacity beyond initial crushing and enhances seismic ductility. Additionally, the concrete resists local buckling of the steel, and the tubes provide ready-made construction forms for pouring the concrete.

Because the present design specification for CFT members accounts for the presence of concrete only by increasing the compressive strength and not the flexural capacity (AISC, 1993), engineers have typically applied CFTs to structural systems where compressive load dominates behavior, such as in mega-braced frames (Griffis, 1992). However, assessing CFT behavior more comprehensively can lead to a better understanding of how to use CFTs efficiently in more common structural systems, including low- and medium-rise moment-resisting frames.

The analysis used to assess CFT member behavior in this research project is a concentrated plasticity finite element formulation which models material nonlinearity through the use of plastic hinges at the member ends (Gourley and Hajjar, 1994). The analysis software, named *cftmacro*, is suitable for conducting "advanced analysis" for direct structural design. Advanced analysis approaches use geometrically and materially nonlinear formulations to calculate structural strength and stability at increasing loads and to determine the load of failure, i.e., the structural limit load. When the structure fails at a load increment at least equal to the factored design load, it is considered to be safely designed. In effect, using advanced analysis for design alleviates the need to perform the tedious design checks specified in building codes for each individual beam and column, since the behavior encompassed by these design checks is assessed directly by the analysis (White and Chen, 1993).

Several comparisons of frame behavior are drawn in this research project—based on geometric frame configuration, lateral load type, design philosophy, and type of column (steel or CFT). Specifically, four different frame configurations are used to determine the effect of geometry on frame behavior and the applicability of CFTs to lower-rise construction. Two lateral load types, wind and seismic, are examined to establish consistency of CFT frame behavior in multiple loading conditions. Finally, a comparison of two design philosophies, the advanced analysis procedure mentioned above, and current Load and Resistance Factor Design (LRFD) procedure (AISC, 1993; NEHRP, 1994), are used to confirm that new, comprehensive design criteria are required to produce efficient CFT frames.

DESIGN PROCEDURE

The four two-dimensional composite CFT frame configurations chosen for the study, representative of low- and medium-rise buildings typical of current construction practice, vary in number of stories, number of bays, bay width, and bay symmetry. This variety allows a comparison of several geometric characteristics using a small number of frames. In particular, the four frames include a three-story frame with two unsymmetric 20- and 30-ft. bays, a four-story frame with four 20-ft. bays, and six- and ten-story frames, each with two 30-ft. bays. All story heights are 13 ft, and all ground supports are fixed. Additionally, the six- and ten-story frames include a stack of leaning columns. The primary purpose of the leaning columns is to increase the mass of the structure, thereby increasing the magnitude of seismic base shear, so that this value compares closely with the magnitude of the wind load, which is unaffected by the addition of the leaning columns. Furthermore, a two-dimensional, steel-only frame design accompanies each CFT frame configuration.

The material properties of each frame were also chosen to reflect current construction standards. The yield strength of the steel tubes is 46 kilo-pounds per square inch (ksi), and the concrete compressive strength is 5 ksi. The yield strength of the columns in the steel frame is 50 ksi, and the yield strength of all steel girders is 36 ksi. The finite element discretization consists of twelve elements per CFT column and eight elements per steel girder in the composite frames, and three elements per column and two elements per girder in the steel frames. All meshes were refined until their solutions converged.

The load on each frame was computed based on current standard design specifications. The same assumptions and calculation procedure were used for all configurations. The unreduced gravity load is representative of typical office building space (ASCE, 1995). The wind and seismic load magnitudes were chosen to produce approximately equal values of base shear and total wind load, to achieve comparable frame behavior under both types of lateral load. The wind load was applied using the procedure outlined in ASCE-7 (ASCE, 1995), and the seismic load was applied using the NEHRP guidelines, assuming a composite special moment resisting frame in computing the response modification factor (NEHRP, 1995).

Each CFT frame in the study was designed using two different design methodologies, which differ in the criteria used to describe failure: second-order inelastic advanced analysis, as described in the Introduction, and elastic-based design according to AISC LRFD (AISC, 1993). Advanced analysis defines failure as a loss of system strength or stability, whereas the LRFD Specification determines failure by comparing the forces present in each individual member to their calculated strength limit states. Each CFT frame configuration was designed using both advanced analysis and the LRFD procedure for the governing gravity or wind load combination, and using the LRFD procedure for the seismic load combination. This resulted in three CFT frame designs for each configuration: an advanced analysis design, a wind LRFD design, and a seismic LRFD design. These designs were each analyzed and the behavior examined under all three load types, including those which did not govern its design. Finally, the steel frames corresponding to each configuration was designed for the governing wind or gravity load combination using advanced analysis, for a total of four frame designs for each configuration.

Girders for all the frames and both design methodologies were designed according to the LRFD Specification, because the advanced analysis model used in this project does not account for lateral-torsional buckling behavior, a likely failure mode for 30-ft. girders (AISC, 1993). An unbraced length equal to half the bay width was used to model a beam framing in at mid-span, and a moment distribution (C_b) factor of 1.75 was used to calculate the nominal girder moment strength for an approximately linear lateral load moment diagram (AISC, 1993). To simplify behavior comparisons, the same girder sizes were retained for all steel and CFT frames in a given configuration, and to retain geometrically-compatible connections, the flange widths of each girder do not exceed the width of the column into which it frames. This requirement also placed an lower limit on the CFT sizes used, often resulting in over-strong upper-story columns.

In advanced analysis design, the target load magnitude derived from code specifications is applied to each frame in proportional load steps until system failure occurs, i.e., the structural limit point is detected. A load factor of 1.11, equal to 1.0 divided by 0.9, the resistance factor specified by AISC for bending, must be reached prior to failure to achieve an adequate design. Using the bending phi factor reflects that system failure is initiated by hinging in the girders, and that column failure, particularly in the CFT frames, is dominated by flexural strength capacity. Member sizes producing system failure at a load factor less than 1.11 prompted an increase in column sizes, and a system load capacity much greater than 1.11 required smaller column sizes.

After changing the column sizes accordingly, the analysis was performed again. During this design procedure, the girder sizes were held constant at their most efficient size based on LRFD.

The LRFD procedure is based on calculating interaction values for each member. These values are derived from forces obtained by a second-order elastic analysis of each frame. Columns exceeding an interaction value of 1.0 are increased in size and the frame is re-analyzed to produce new forces and re-check interaction values. Effective length (K) factors in the non-leaning frames were based on the nomograph in the LRFD Commentary Section C-2, and story-based K-factors were used for the leaning frames (AISC, 1993). In addition, the strong-column, weak-beam provision specified by AISC (1992) was applied to the seismic designs.

A linear elastic analysis was performed on each final frame design to determine inter story drift profiles. The limit of inter story drift for wind load was taken to be the story height divided by 400, using a reduced wind load (Ellingwood, 1996). The drift limit for seismic load was determined to be the story height divided by 50, using a drift amplification factor of 5.5, as defined in NEHRP Table 2.2.2 for special composite moment-resisting frames (NEHRP, 1995).

RESULTS

The resulting frame designs are summarized below, followed by an assessment of their behavior. Behavior is compared on the basis of load type, design methodology, and material used (i.e., steel or CFT columns). Results of the six-story frame design are shown in Figure 1. Detailed results of all frame designs may be found in (Fetterer and Hajjar, 1997).

In general, the design of the four CFT frame configurations was governed by different load combinations, but within a given configuration, similar load types governed the different designs of that frame. All three three-story CFT frames were governed by the gravity load combination. The load which governed failure of the four-story, four-bay frame designed by advanced analysis varied between stiffness limitations, the gravity, and the wind load combination, depending on the particular member proportions. .The chosen design was governed by stiffness. The four-story LRFD wind frame was governed by the gravity load combination, and the seismic load combination governed the four-story LRFD seismic frame. The six-story frame was governed by stiffness limitations for the advanced analysis and LRFD seismic designs, and by the wind load combination for the LRFD wind design. All ten-story frames were governed by stiffness limits.

The strategy for reducing CFT frame drift with minimal increases in member size differs according to the configuration in question. For the ten-story frame, increasing girder sizes contributes a great deal to stiffening the frame, but increasing the CFT sizes is more effective in reducing drift on the six-story frame. Drift in the three- and four-story frames is minimal, due to the shorter total frame height and the increased system stiffness provided by the additional bays.

Lateral Load Type Comparisons

Different lateral load types caused differences in both frame design and frame behavior. Designing the CFT frames using the LRFD procedure produced comparable member sizes for wind and seismic loading conditions, but different member proportions along the frame height. Rapid increases in load magnitude along the height of the frame, characteristic of a seismic load distribution, causes column forces inversely proportional to the decreasing gravity force, and a relatively constant total demand on each column along the building height. Therefore, column sizes are more uniform along the height of the frame and thus larger in the upper stories of the LRFD frames designed for the seismic load combination than the LRFD wind-designed frames.

The behavior differences within a given CFT frame design subjected to two different lateral load types was measured by drift profile, sequence of plastic hinge formation, and load factor at failure. Wind load causes the highest values of inter-story drift at the first or second story, which taper off to small values at the upper stories. Conversely, seismic load causes approximately uniform inter-story drift values along the frame height, with the most severe values occurring in the upper stories. This difference can be attributed to the difference in load distribution—the seismic load is more concentrated at the upper stories than the wind load distribution. High seismic load values at the upper stories can also account for seismic load causing maximum drift values about twice the magnitude of the maximum drift due to wind load, despite approximately equal values of seismic base shear and total wind load.

Differences in the sequence of plastic hinge formation are not easily distinguished between the two load types, confirming similar behavior of CFT frames under both lateral load types. In general for the CFT frames under both wind and seismic load, the first girder hinge occurs at a load about 20% less than the load causing the first column hinge. This strong-column, weak-beam behavior is generally a preferred failure mechanism for any load combination, so that conspicuous girder rotations precede catastrophic collapse. For these frames, the initial column hinge caused by the wind load combination is generally a first-story central column, also the most frequent location of critical inter-story drift. The first column hinge to form under seismic load is generally at the top story, where the load magnitude is highest. Additionally, for most CFT frame designs, the first column hinge occurs earlier in a wind load history than in a seismic load history, even though in many frame designs, seismic load causes failure at a lower load factor than wind. This again indicates the greater spread of column demand under wind load—as the "weaker" columns slowly shed load to the "stronger" columns, the failure load increases.

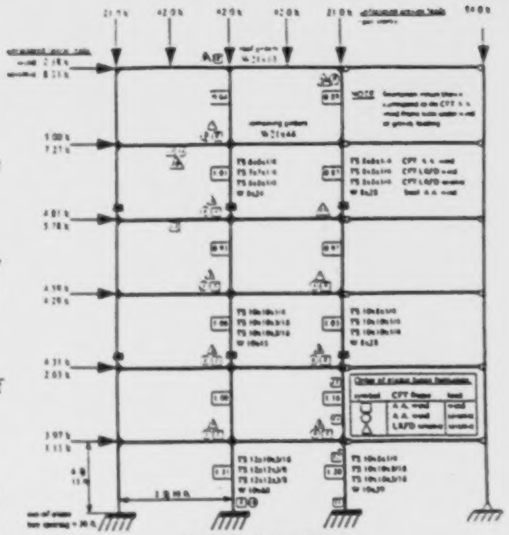

Figure 1: 6-story frame

Design Methodology Comparisons

Differences in CFT frame behavior based on design methodology are primarily a result of the overall difference in member sizes. When the LRFD design criteria are applied to the advanced analysis design member sizes, interaction is breached for several columns in all configurations. The degree to which the configuration was controlled by stiffness, i.e., the greater the overstrength of the frame, the fewer advanced analysis columns breach interaction. For example, about one quarter of the CFTs in the ten-story advanced analysis frame breach interaction, whereas more than half the CFTs in the six-story frame breach interaction. These inflated interaction values indicate that the LRFD procedure underestimates ultimate CFT capacity, and sizes stronger and larger than necessary are used in CFT frames designed with LRFD. The degree of CFT overstrength in the LRFD frames is further implied by a global increase in total steel weight on the order of 20% compared to the frames designed using advanced analysis.

Another indicator of overstrength is that when the final LRFD frames were analyzed under the load type for which they were designed, failure was detected at a load factor substantially greater than 1.0. This value was as great as 1.73 in the 10-story frame designed for seismic load, where the member size differences between the two design methods are large. However, the degree of overstrength is only 1.20 in the 3-story frame designed for gravity load, whose girder sizes, which are the same in both the LRFD and advanced analysis frames, are the trigger for failure. Overstrength is further shown by the fact that stiffness limitations govern only the design of the ten-story LRFD wind frame, and that column hinges form at 30% higher loads in the LRFD frames than in the advanced analysis frames.

CFT Comparisons to Steel

Since steel frames corresponding to each configuration were designed only for wind load using advanced analysis, comparisons drawn between steel and CFT frame behavior are limited to the two advanced analysis frames. The design of the three- and four-story steel frames were governed by gravity load, and the six- and ten-story steel frames were governed by stiffness limitations. Steel weight of the wide-flange columns exceeds the steel weight of the CFTs by 20 to 30%, with the greatest difference occurring in the ten-story frame. Plastic hinge formation in the girders follows a similar sequence in both frames, but a comparison of column plastic hinge formation is not meaningful due to different cross-sectional material models.

Differences in drift profiles between the steel and CFT frames exist for all configurations—although both profiles show less inter story drift at the upper stories than at the lower stories, the CFT frames exhibit sequentially greater inter story drifts along the frame height than the steel frames, causing a greater total lateral drift. The taller frames exhibit a greater drift difference. The methods used to control drift in the design of the steel and CFT frames differed in a manner similar to the different drift control strategies among the various CFT frame configurations. Whereas increased girder sizes contribute more effectively to drift control in the steel frames, increasing column sizes is more effective at reducing drift in the CFT frames.

CONCLUSIONS

Characteristics of CFT frame behavior can be shown through comparisons of design methodology, frame configuration, load type, and a comparison to steel frame behavior. Because the current CFT design specification is based on rudimentary behavioral assumptions, some of the most distinguishing CFT frame characteristics are shown by comparing frames designed using LRFD and advanced analysis design methodologies. Large differences in member sizes between advanced analysis and LRFD design methods indicate that the current specification substantially underestimates CFT capacity. In particular, the extent of CFT flexural capacity is poorly accounted for. This is exhibited most clearly in the six-story configuration, where the LRFD design is governed by individual member strengths under wind load, but the advanced analysis design, which accounts more explicitly for CFT behavior, shows that a frame consisting of significantly smaller columns contains enough resistance to lateral load that its design is strongly governed by stiffness and not strength limitations.

CFT behavior is also indicated in a comparison of CFT frames to similarly-proportioned steel frames subjected to identical loads. Although the overall weight of steel is less in the CFT frames, this alone is not an accurate measure of structural economy, because CFT connections are not yet standardized and are thus often expensive. A more important difference between CFT and steel frames is the difference in lateral stiffness. Despite CFT flexural strength greater than the predicted code values, CFT flexural stiffness, as indicated by lateral drift of the frame, is still less than that the stiffness of steel wide-flange members of comparable major-axis flexural strength. This results in CFT designs controlled by stiffness for any frame not dominated by gravity load, even for an inherently stiff frame such as the four-story, four-bay frame.

Perhaps a more precise indicator of CFT behavior than pure flexural strength or stiffness is the ratio of flexural strength capacity to axial capacity. This ratio is fundamentally different for CFTs than for steel, and it must be accounted for in design. CFTs can be efficiently applied to highly gravity-dominant structural systems with the current design specification. But in order to produce efficient CFT frame designs applicable to low- and medium-rise moment-resisting frames and other common building structures, a new approach to CFT design, such as drift-based criteria which accounts for this decreased flexural capacity ratio, must be adopted.

Removal of Ammonia from Contaminated Air Stream by Biofiltration

Ruihong Zhang

Ammonia, a trace gas component in exhaust gas from wastewater treatment processes, must be removed because of its odorous nature. Biofiltration, with rice straw and microorganisms as the media, was chosen to clean the gas stream due to its possibility of removing the odorous gases from the gas stream at low cost and high efficiency. In the process of biofiltration, ammonia is transferred from the air stream to biofilm when ammonia and air pass through a microbiologically active filter bed, made of rice straw, and are metabolized by the embedded microorganisms, nitrifying bacteria which grow on the nitrogen supplied by the gases and the carbon supplied by the rice straw. With a 60% moisture content, pH 7±0.4, 6.5L/min air loading rate, and room temperature 20°C±1.0°C, there was a 95% ammonia removal efficiency for a duration of 30 days. The moisture content was found to be the most important parameter in this experiment since high moisture content increases the rate of degradation of the rice straw.

INTRODUCTION

Odors from wastewater treatment facilities are problems that have affected citizens for decades (Hwang, 1994). A 1978 wastewater treatment plants (WWTPs) survey showed the complaints about odors from WWTP activities (Langenhove, 1985). Since then removal of odorous gases from wastewater treatment plants has become one of the major areas that scientists focus on. Ammonia, produced as a trace gas component during wastewater treatment processes, must be removed from exhaust gas because of its odorous nature (Hwang, 1994). Various physical and chemical treatment processes, such as activated carbon and electrochemical membrane separator have been used to purify the exhaust gases from wastewater treatment processes. However, because of the large operating costs of these systems, biological processes have been developed. These processes may serve as an environmentally and economically sound alternative because of their low operating cost and minimum environmental impact.

Biological processes have been widely used for management of ammonia in exhaust gas from the wastewater treatment plants. Several studies on the biological filter that removes the odorous gases have been done (Hartikainen, 1996, Basu, 1994, Liu, 1994, Gadre, 1989, Langenhove, 1985). In our laboratory, we chose the method of biofiltration because it removes ammonia gas at high efficiency. The biofilter uses a filter media that consists of rice straw and microorganisms (nitrifying bacteria) to absorb and degrade ammonia nitrogen. The purpose of this study is to investigate the uses of low cost rice straw and nitrifying bacteria to purify ammonia contaminated air stream.

MATERIALS AND METHODS

Experimental Set-Up

A schematic diagram of a laboratory scaled biofiltration system is shown in Fig. 1. The bioreactor (height: 18.75 in, cross sectional area: 0.013 m^2) was packed with a media of ground rice straw (1 inch in length) and microorganisms (1/3 of the mass of the wet weight of rice straw). The ammonia gas stream supplied to the biofilter was generated by purging a pure air stream through deionized water (to provide a constant humidity to the system) and diluted ammonia hydroxide solution. All experiments were carried out at room temperature, 20±1.0°C.

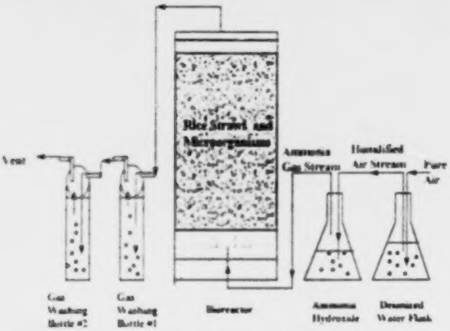

Figure 1. The experimental schematics

Biofilter medium

The rice straw used as the packing material was 1 inch in length with a 10% moisture content. The percentage moisture content was determined by drying in oven at 103°C for 12 hours. Table 1 shows the results of elementary analysis of the rice straw.

Wastewater containing nitrifying bacteria was obtained from the wastewater treatment plant at the University of California Davis and used as the seed culture of nitrifying bacteria for our biofilters.

Table 1. Some properties of the rice straw

Item	Value
pH	6.7
Moisture Content (%)	10
C (%)	34.9
N (%)	0.674
Ash (%)	20

Preparation of rice straw seeded with nitrifying bacteria and operational procedures

The rice straw was mixed with the wastewater that contained an unknown amount of nitrifying bacteria (this will be investigated in our future work). With a 5% suspended solids content, the quantity of the wastewater was 1/3 of the wet weight of the rice straw. After mixing the rice straws and the wastewater, the moisture content of the rice straw was raised to about 60% by adding additional deionized water. Then the moisture content was controlled at this level by the humidified air stream. The weight of the packed rice straw was 695g. The packing volume was 5.86L, and the starting pH was about 6.7.

The air loading rate of the inlet ammonia was 6.5L/min; the ammonia hydroxide solution, made by mixing 0.789mL of 58% concentrated ammonium hydroxide and 500mL of deionized water, was changed every 24 hour to supply ammonia gas to the biofitler at relatively constant level of 20 ppm in the air. The amount of deionized water in the water flask was kept at 1000L to provide a constant humidity. Samples of rice straw were taken from the biofilter once a week for analysis of percentage moisture content, pH, and total nitrogen and total carbon.

Ammonia Adsorption Analysis

The amount of ammonia in the NH_4OH solution at inlet gas stream and boric acid at the outlet was determined by a calibrated ammonia probe. The calibration was performed with five standard ammonia solutions (10mg/L, 50mg/L, 100mg/L, 500mg/L, and 1000mg/L), which were prepared by diluting 1000mg/L NH_4Cl solution with deionized water (for testing the inlet gas) and with boric acid (for testing the effluent gas). The procedures for calibration and measurement were from the instruction manual of the ammonia probe. The effluent gas was collected three times a week by two connected gas washing bottles containing 0.3M boric acid, which was prepared by dissolving 18.6g of boric acid powder in 1000mL of deionized water. The ammonia efficiency was calculated by formula (1).

$$\frac{\text{(Amount of Ammonia entered - Amount of Ammonia in Boric Acid)}}{\text{Amount of Ammonia entered}} \qquad (1)$$

RESULTS AND DISCUSSION

Determining the Optimal Moisture Content for the Biofilter Media

Two trials were conducted to determine the optimal moisture content for the biofilter media. In trial I, the moisture content was controlled at 80% for a three-week time period. In trial II, the moisture content was lowered to 50% for another three weeks. Both experiments were conducted under the same temperature (20°C±1.0°C), air loading rate (2.5L/min), media, and packing volume except the moisture content. After three weeks, a sample from each trial was sent to DANR Laboratory at UC Davis for percent carbon analysis. The product of the total mass and the percentage of lost carbon yielded the total carbon loss. With 80% moisture content, the total carbon content in the rice straw decreased about 6% with 177.1g carbon loss. With 50% moisture content, the total carbon content in the straw decreased by 2.5% with 26.9g loss. Table 2 shows the results from percent carbon analysis and total carbon loss calculation. The middle column shows the differences in percentage carbon in rice straws at the beginning (fresh rice straw) and the end of each trial; the third column shows these differences in unit of mass. The data shows that in Trial 1 there was a higher rice straw degradation. To extend the life of the media, we needed to choose a moisture content that contributes to a lower carbon loss. From our moisture content analysis and literature review (Langenhove, 1985), a 60 percent moisture content was chosen as the optimal condition for the filter media.

Table 2. Comparison of Rice Straw Degradation

Item	Δ %C	Δ C-Tot Loss
Fresh Rice Straw	34.9	-
Trial I (80%)	28.8	177.1 g
Trial II (50%)	32.4	26.9 g

Ammonia Removal Efficiency of Rice Straw Filter

A third trial was conducted for 46 days for ammonia removal testing. The experiment was conducted under the following conditions: pH 7±0.4, 60% moisture content, 20 ppm inlet ammonia concentration, 6.5L/min air loading rate, and 20°C±1.0°C room temperature. Two biofilters were set up with the same conditions as illustrated above but with different media. Reactor 1 contained ground rice straw, and Reactor 2 contained ground rice straw and soil particles that were used as the sources of nitrifying bacteria. The mass ratio between ground rice straw and soil particles was 3:1. Three sets of experimental data were obtained every week from the ammonia adsorption analysis of ammonium hydroxide solution and boric acid solution. The ammonia removal efficiency was determined by measuring the amount of ammonia that entered into the bioreactor, and the amount collected in the two gas washing bottles. The difference between the two would be the amount removed by the bioreactor. According to experimental results, Reactors 1 and 2 both removed ammonia with an efficiency greater than 95% for 30 and 36 days, respectively. Afterwards, the ammonia removal efficiency dropped dramatically. Figure 2 demonstrates clearly the differences between the two reactors. The one-week longer life time for Reactor 2 (rice straw with soil particles) is a consequence of the media's higher porosity, which provides more active sites for ammonia to bind to the media. Moreover, pure rice straw filter has larger air spaces for ammonia gas to escape thus lowering the ammonia removal efficiency. In order to prove that the biofilter really removed the ammonia gas, we sent in our weekly collected rice straws samples to the DANR Analytical Laboratory at the University of California Davis for nitrogen and carbon analysis. Figures 3 and 4 show the results of the analysis for Reactor 1 and Reactor 2, respectively. Both graphs show carbon loss and nitrogen build-up as the experiments proceed. Therefore, we can conclude that the media in the biofilter removes the ammonia.

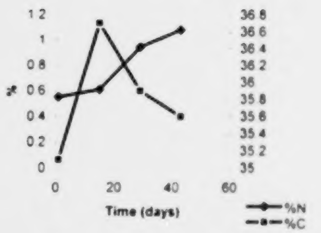

Figure 3. Changes in %N & %C in R1 (rice straw)

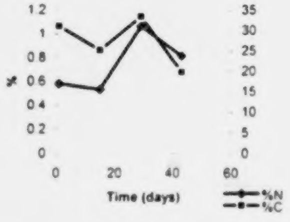

Figure 4. Changes in %N and %C in R2 (rice straw and soil particles)

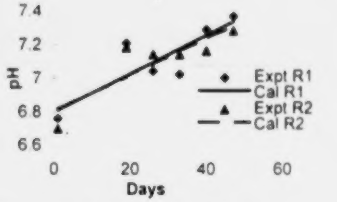

Figure 5. pH changes for both reactors

Effects of pH on Rice Straw Filter

pH of the media was measured every week by pH probe. The data we obtained through the 46-day experiment led to the graph below. Figure 5 shows a similar trend of increasing pH appeared in both reactors. Since the pH did not dramatically increase or decrease during the 46-day experiment, we concluded that pH did not affect our experimental conditions.

CONCLUSION

a) Optimal Experimental Conditions

Rice straw was found to be a good packing media for biofilters. At 60% moisture content, pH 7±0.4, 20ppm ammonia concentration in air, 6.5L/min air loading rate, and

20°C±1.0°C room temperature, there is a 95% removal efficiency lasting 30 days for pure ground rice straw and 36 days for rice straw with soil particles. Afterwards, the ammonia removal efficiency drops dramatically, indicating the break-through of filter media by ammonia. The moisture content of the packing media is a very important factor in this experiment since high moisture increases the degradation rate of the rice straw, therefore reducing the life time of the filter media. The optimal moisture content of filter media is 50-60%.

b) Soil Addictive Media

From the results we obtained, we conclude that rice straw with soil particles is a very economic filter media for the removal of ammonia from exhaust gas. First, rice straws with soil particles provide larger surface areas and active sites for ammonia to bind. Second, the air permeability of rice straw is better than other filter media such as fiber peat and household compost. Lastly, rice straw and soil particles can be obtained easily at low cost in geographical areas where rice is a dominant crop.

c) Future Work

From the difference in the efficiency of ammonia removal between rice straw and rice straw with soil particles, we predict that the amount of nitrifying bacteria in the media will have a substantial influence on the removal efficiency. It will be investigated in our future studies

COMPARISON OF ANALYSIS METHODS FOR NON-CLASSICAL STRUCTURES WITH ADDED VISCOELASTIC DAMPING

Douglas K. Nims

Earthquakes cause extreme damage to building structures. Therefore, it is necessary to be able to predict the response of structures during earthquakes. In predicting the response, the structure must be represented mathematically by its mass, stiffness, and damping. Normally, these properties are simplified for ease of analysis. In the case of non-classically damped structures, these linear approximations are not valid due to the sharing of energy between different structural resonant frequencies, or modes. As the response of non-classic structures must be predicted to ensure their safety, over the years different analytical models have been developed to approximate the mass and damping for such structures. Presently several analytical models exist, but few experimental tests have been performed to verify them. The focus of this project was to compare the responses obtained from the analytical models with experimental results. A non-classical three degree of freedom building structure was designed. Added viscoelastic damping (through material 3M-ISD-112, provided by 3M, St. Paul, MN) was implemented to accentuate the modal coupling. Impulse loading and harmonic input testing was done on this structure with four damping arrangements. Experimental values of response were compared with like values found through modal analysis and the Wilson-θ method.

PROJECT OBJECTIVES

The general structural dynamic equation is given by (1):

$$M\ddot{u} + C\dot{u} + Ku = P(t) \qquad (1)$$

,where M=mass matrix, C=damping matrix, K=stiffness matrix, $\ddot{u}$ =acceleration vector, $\dot{u}$ =velocity vector, u=displacement vector, and P(t) is the time dependent forcing function vector.

In structures where the resonant frequencies, or modes, are close together (within 10-20%), energy is transferred through the structure between the adjacent modes. This causes the damping matrix to be non-orthogonal, rendering modal analysis, the "classic" method of dynamic analysis, an ineffective solution method. Therefore, structures with non-orthogonal property matrices are referred to as "non-classical." The non-orthogonality of the damping matrix can be increased through additional structural damping.

Alternative dynamic analysis methods include the direct solution of Eq. (1) and iterative procedures. Solution by direct solution is very mathematically difficult and time consuming. Iterative methods involve looking at the change in the motion of the structure considering very small time intervals. With many iterative methods it is possible to use property matrices of any orientation, including non-orthogonal. The iterative method used thus far for comparison is the Wilson-θ method (Wilson, et al, 1973).[1] The Wilson-θ method is an expansion of the linear acceleration method, approximating the acceleration with the change in force with respect to a value of θ ($1.37 \le \theta \le 1.42$).

The scope of this project included the design and construction of a miniature building frame with close modes (within 3%), a damper series, instrumentation and data acquisition, testing, computer modeling, and analysis. Experimental response ($\ddot{u}, \dot{u}$, and u) was compared with the responses obtained using modal analysis (using SAP90, Computers and Structures,

BEST COPY AVAILABLE

Inc., 1990) and Wilson's method. In this project, additional damping was provided through the use of 3M (St. Paul, MN) viscoelastic material, a polymer that provides both energy dissipation (behavior similar to a viscous damper, visco-) and restoring force (-elastic).[2]

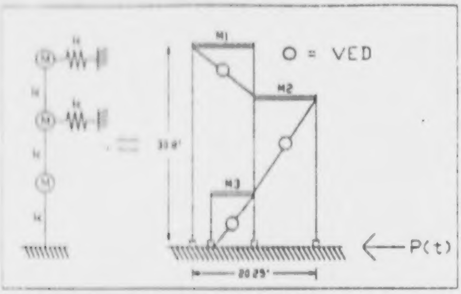

Figure 1: Modeling Concept and Physical Design

TESTING AND RESULTS

The model was tested without dampers and with three damper design series: 3%, 6.5%, and 10% critical damping. An unpredicted stiffening effect of the viscoelastic material was encountered after construction of the dampers and before testing. This caused the actual damping ratios to be closer to 4%, 10%, and 9%, respectively.

Instrumentation consisted of accelerometers (Setra, Inc.) at each building floor and the table surface. Data was collected at the rate of 200 points per second. Testing was performed on a 30 inch square RV-30-300 (L.A.B. Corporation) vibration testing table, or "shake table".

Sine sweep tests were run using the harmonic loading produced by the shake table. As the frequency of the table increases, the magnitude of the force also increases, the outline of the periodic force therefore resembling the sine function. The table was made to run systematically from 5 Hz to 30 Hz, and back down to 5 Hz. Therefore, the input acceleration passed through the modes of the frame, giving response amplitude peaks at these points. Also, each experimental test had approximately the same input motion, as the increase in frequency and amplitude was regulated by a cycling motor.

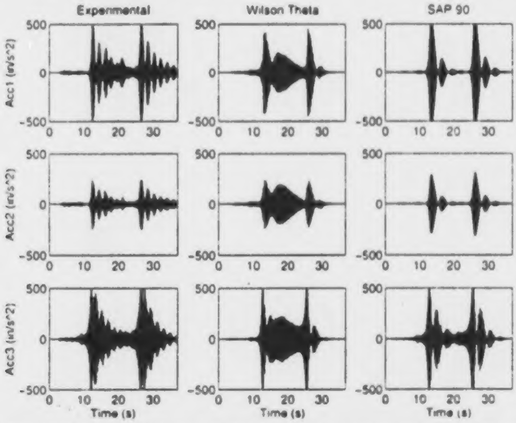

Figure 2: Undamped Sine Sweep Test With Analytical Comparisons

Figures 2-3 show experiment runs for the undamped run, and the 4% damping run, which was similar in shape to the 9% and 10% damping runs. Presented alongside the experimental plots are the acceleration response values computed by the analytical methods used. The nonclassical damping matrix used in the Wilson-θ method calculations was found using a relationship between the mass matrix and mode shapes (Clough and Penzien, ch. 13).[3] The notation used to code the Wilson-θ method was found in Bathe (1995).[4]

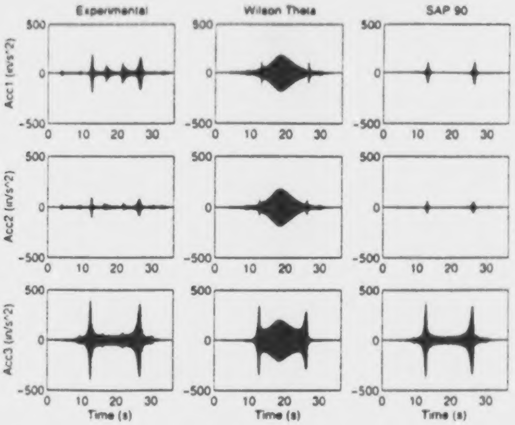

Figure 3: Four % Damped Sine Sweep Test With Analytical Comparisons

CONCLUSIONS

In viewing Figures 2 and 3, notice that when the damping is small the experimental response resembles the modal analysis response (SAP90), and when the damping is greater the response is more comparable with the Wilson method. This follows the fact that increasing damping increases the modal coupling, and therefore makes the damping matrix non-classical to a greater extent.

Also demonstrated in these figures is the great reduction in the magnitude of the acceleration response due to the addition of viscoelastic damping at only 4% of critical. Design viscoelastic damping is often in the range of 10%-20% of critical.[2] Note also that this reduction is done without greatly influencing the structural behavior (modes), or weight of the structure. These properties make viscoelastic material an attractive alternative to energy dissipation methods such as steel dampers or frictional damping, as the original structure can be protected without being radically changed in increasing weight, or vibration characteristics.

It can be seen In Figure 3 that although the response obtained with the Wilson method does not directly compare with the non-classical structure, both responses include modal coupling. It is clear that the SAP90 analysis includes no modal coupling, and only produces amplitude peaks at the resonant frequencies of the frame. Reasons for a non-exact solution could be due to one of the diagonal braces coming partly detached (which did occur), the shear failure of the viscoelastic material bond, the influence of the instrumentation wires on the frame, or misrepresentation of the frame mathematically.

Future testing should include the measuring of the dynamic damping per cycle through hysteresis loops. Investigation will also be undertaken on the undefined source of the dampers stiffening with time. Also, other iterative methods should be compared with the experimental response as well.

ACKNOWLEDGMENTS

Portions of this project were funded by the Ohio Space Grant Consortium, the University of Toledo Research Council, and the University of Toledo Honors Program. Thanks are also due to Dr. Ming Lai and Dr. Dwayne Lunsford at 3M, and also to Rob Dunmyer of the Civil Engineering Department at the University of Toledo.

Stone masonry arches were a very common type of bridge built in the northeast U.S. during the 18th and 19th centuries. To the dismay of many, they are slowly falling victim to the increasing vehicle weights and volumes of today's roadways. Therefore, there is an urgent need for an effective and economical method of rehabilitating these structures.

This presentation will display the results of a series of load vs. displacement tests that were done on a bridge that was rehabilitated using recently developed techniques. The displacement data was used to rate the effectiveness of the repairs and to determine a load rating for the bridge.

INTRODUCTION

On April 12, 1996 a series of tests were conducted on the Wyebrook bridge, a stone masonry arch bridge in Chester County, PA. These tests were done in order to determine the deflection under loading of the bridge at several locations. This information was then used to evaluate the success of a recent rehabilitation, estimate the loading capacity of the bridge, and determine the need for a weight restriction.

BACKGROUND

Description of the Structure

The Wyebrook bridge is a three-span stone masonry arch bridge that carries Wyebrook road over Brandywine Creek. It is located in West Nantmeal Township, Chester County, Pennsylvania. The structure was originally constructed in 1888 and later rehabilitated in 1995 after a partial collapse of the spandrel wall and the arch at the southern approach.

The bridge consists of three arches. The two smaller approach arches each span 13'-1" and are semi-circular. The center arch is larger, spanning 25'-3", and has a four-centered configuration. The spandrel walls are approximately two feet thick and composed of roughly dressed random stone. The spandrel wall extends 7'-1" above the intrados at the crown of the center arch, providing a parapet that is 3'-7" high. The entire length of the structure along the top of the parapet is 100'-6".

Condition of the Structure

The center arch was probably built with the four-centered configuration in an attempt to limit the height of the structure. However, this created a "humpback" in the roadway above this center arch. At the time of the bridge's construction, this would not have posed a problem to horse-drawn carriages. However this hump in the road proved to be a danger as vehicle speed increased. Eventually, the grade at the south side of the bridge was raised to eliminate the humpback and create a uniform grade of 5%. An estimated 4 feet of clay fill was added, and the spandrel wall at that approach was extended (Boothby and Craig, 1996).

Other than a troubling pattern of cracking documented in inspection reports, the bridge appeared to be structurally sound. There was no evidence of scour or settlement of the foundations. There was also no apparent bowing or sagging of the arch rings, which would indicate hinging (Baker, 1907). As cracking problems increased, a minor rehabilitation was scheduled for 1995 (Boothby and Craig, 1996).

During the night of August 22, 1994, after a prolonged period of heavy rains, the spandrel wall over the south approach span collapsed under hydrostatic pressure. A large part of the arch ring also fell. The bridge was immediately closed to traffic and inspected thoroughly. Some smaller longitudinal cracks were discovered in the center span underneath the intact spandrel wall. Although these were not progressing at the rate of those in the collapsed ring, a portion of the spandrel wall and the exterior face of the center arch ring was removed to be reconstructed along with the collapsed portion of the spandrel wall and approach arch (Boothby and Craig, 1996).

The undamaged portions of the bridge were left intact and only the collapsed portions of the bridge were rebuilt. Because the arches had proved to be sound in the longitudinal direction, a plan to build reinforced concrete saddle arches was rejected in favor of a less expensive plan that addressed the need to alleviate the hydrostatic pressure on the spandrel walls. First, the clayey silt fill was replaced with an engineered fill material meeting PADOT specifications for structural backfill, 2A modified. This material is free-draining and has a higher angle of internal friction than the previous fill, so both hydrostatic pressures and active earth pressures were reduced significantly. Reinforced concrete walls were then constructed inside the original spandrel walls over the area where the grade had been raised; half of the main span and the entire approach span. These reinforced concrete walls were then connected with cables anchored with eyebolts to the walls at a spacing of 10 feet horizontally and four feet vertically (Boothby and Craig, 1996).

The replacement of fill and reinforcement of the spandrel walls proved to be economical, but a continued monitoring program has been determined to be necessary to ensure that the repairs successfully restrained the spandrel walls from moving outward.

LITERATURE REVIEW

Due to the unique circumstances behind this testing program, very little literature is available that is directly relevant to this report. Several in-service structures in the eastern United States have been tested to determine their load capacity. Tests to collapse have been done on full scale and reduced size models. Several in-service bridges have been tested to collapse in the United Kingdom, and a few recently constructed or rehabilitated structures have been instrumented to allow monitoring. The relevant portions of several papers related to these programs are discussed below.

Masonry Arch Bridges, a state of the art review (Page, 1993), provides a comprehensive survey of current knowledge in every aspect of stone and brick masonry arch bridges. Of particular relevance to this study, Page includes an extensive examination of common repair and maintenance problems experienced by older masonry arch structures. Movement of the spandrel walls is a frequent ailment of masonry bridges, and was the main mode of failure of the Wyebrook bridge. The other problem exhibited in the Wyebrook bridge was that the clay fill failed to drain sufficiently. This problem is also cited by Page as a case of inadequate waterproofing. Suggested repair techniques listed include placing tie bars to restrain the spandrel walls and replacing the fill with concrete. The rehabilitation plan undertaken at Wyebrook included the tied spandrel walls in addition to a pair of reinforced concrete auxiliary spandrel walls. What Page fails to mention is the replacement of the clay fill with engineered fill as was used at Wyebrook. This solution is less costly than replacement of the fill with concrete.

The TRRL Report entitled "Test on Stone Masonry Arch at Bridgemill-Girvan" (Hendry and Davies, 1985) is an account of a test to failure on an existing masonry arch bridge. The authors used several methods of analysis to determine the failure loads of the bridge and then compared these results to the results of the actual test to failure. Many of these analysis methods rely heavily on engineering judgment and were therefore found to be overly conservative in their estimates of failure load. The authors of this report observed that the bridge deflected linearly with respect to loading up until the load reached approximately one third of the failure load. They therefore suggested a form of non-destructive testing that could be carried out on bridges that are currently in service. If displacements are measured at several different levels of loading and the bridge appears to exhibit a linear response, then no significant damage has been done to the structure and one third of the ultimate capacity of the bridge has not yet been reached. This is the justification for the testing that was done on Wyebrook and the logic behind the conclusions that were drawn from the test data.

The proceedings of the *First International Conference on Arch Bridges* held at Bolton, UK in September of 1995 are contained in *Arch Bridges* (Melbourne, 1995). The papers presented at the conference provide a wealth of information on the arch bridges, but only a few are directly related to the subject of this report. Several of these papers are addressed below.

In his paper entitled "Load Tests for Assessment of In-service Arch Bridges" (Page, 1995), Page asserts that load tests of in service bridges could be used either in conjunction with other analysis methods or as a valid test method in and of itself. He also states that "the UK Department of Transport view is that load tests. . . should not be considered as replacements for usual assessment procedures." Load testing on the bridge often predicts a greater load capacity

1072

and may therefore be beneficial to the owner. He suggests that a range of loads be applied during the testing to ensure that the response is linear as a safeguard against damage.

In a paper entitled "Renovation of Masonry Bridges" (Welch, 1995), Welch summarizes many of the common problems experienced by masonry bridges and suggests methods of repair for these problems. Among these repair methods, reconstruction of the spandrel wall reinforced with a reinforced earth system supporting the fill is suggested. Welch warns against backing the spandrel walls with concrete because this creates a deep, stiff beam edge on the arch, which is inconsistent with its intended structural behavior.

The final paper from the International Conference on Arch Bridges that will be discussed here is entitled "Assessment of Masonry Arch Bridges by Service Test Loading" (Boothby et al. 1995). This paper presents the results of five separate load tests on in-service stone masonry arch bridges in various states of disrepair. The procedure described in this paper is nearly identical to the procedure used in the testing of the Wyebrook bridge. The bridges were loaded with trucks of various weights and displacements at several locations were measured with linear variable differential transformers (LVDT's). These results were interpreted in conjunction with a finite element analysis package to determine the structural integrity of the structures.

A similar series of tests were conducted at Bridge No. 270, a random stone masonry arch bridge in Chester County, PA (Boothby and Domalik, 1994). Results from load testing were compared to results from a finite element analysis and used to assess the capacity of the bridge. The displacements of the arch were linear with respect to loading and no damage was cause by the test. However, the lateral movement of the spandrel walls was non-linear, and permanent deformations were caused by the loading. Recommendations were made to the owner that weight restrictions be placed on the structure and repairs be made immediately.

A report entitled "Stone Arch Bridge Repair: A Case Study" (Boothby and Craig, 1996) discusses the history, failure, and subsequent rehabilitation of the Wyebrook bridge in Chester County. Much of the background presented in this paper was obtained from the report by Boothby and Craig. This paper actually presents the results of the monitoring program recommended by Boothby and Craig.

PROCEDURE

Instrumentation

A pair of light steel frames was constructed along the bridge's spandrel walls. These frames extended from the edge of the parapet along the south approach span to the center of the southern approach arch. Another reference frame was also set up at the edge of the stream on the southern side of the main arch at the west spandrel wall, near the location of a longitudinal crack in the arch barrel. Additionally, a frame was built directly under the southern arch.

Ten linear variable differential transformers (LVDT's) were clamped at various points on these frames and used to measure the deflections of the bridge under loading. Eight of the LVDT's were attached to the reference frames along the spandrel walls in order to measure horizontal movement of the walls. One LVDT was placed directly under the southern approach arch to measure vertical displacement of the arch. The last spanned a longitudinal crack just below the spandrel wall in the main arch to detect widening of the crack.

In addition to the LVDT's, five strain gauges had been attached, during the reconstruction of the bridge, to the eyebolts that anchored spandrel walls together. The strain gauges were also connected to the computer during the testing so that the strain on the cables connecting the concrete walls could be read.

Test Procedure

During the different tests, a truck of known weight was driven over the bridge at various locations with respect to the centerline of the roadway. For each test, the truck started at the center of the bridge and backed slowly to the south abutment, then returned to the center of the bridge. The location of the truck along the bridge was to be measured during each test by a linear motion transducer. Unfortunately, this piece of equipment malfunctioned during the first test. For the remaining tests, a trigger mechanism was used to spike the voltage when the truck passed cones placed at 25' intervals on the road.

Each individual test has been given a name that indicates the nature of that test. The first letter in the test name indicates the weight of the truck that was used.

E = empty truck (30,350 lb.)
H = half full truck (50,350 lb.)
F = full truck (69,600 lb.)

The characters in the middle of the name indicate the location of the truck along the road.

R = right (east) side, along parapet
R48 = 48" from the parapet on the right side
L = left (west) side, along parapet
L--a = the truck ran along the entire length of the bridge on the left side

RESULTS

The nature of this paper prevents a complete listing of results. Table 2 is an example of the magnitude of displacements observed in the spandrel walls during a pass of the full truck.

* Tests began late ** Generally unreliable instruments
Shaded entries are results that are known to be unreliable.

OBSERVATIONS

Wind Effects

As can be seen from the above table, many of the tests have been declared unreliable. The reason for this is the effect that the wind had on the frame used to anchor the instruments measuring the movement of the spandrel walls. Many of the tests showed erratic and completely random movement that could not have been the result of movement of the spandrel walls.

Timing Effects

The malfunction of the linear motion transducer also influenced the overall quality of the results. Because the trigger mechanism relied on human reaction to the truck passing by a cone, no completely reliable indication of the truck's location was obtained. This made precise analysis of the displacement data with respect to the location of the truck impossible.

As a result of inaccuracy in triggering the test, the computer began collecting data during each of the tests with the truck at a different point on the bridge. This inconsistency produced final displacement readings that are misleading. When the computer began collecting data after the truck had been in motion for some amount of time, the displacement had already started when the computer began collecting the data. In many cases, this resulted in an erroneous negative final displacement. Also, the magnitude of the maximum displacement misrepresents the total amount of motion that occurred. In these cases, the actual displacement must be found by adding the absolute values of the maximum positive and negative displacements.

Comparison

When the valid results from these tests are compared with the tests done on bridge #270 in Chester County (Boothby and Domalik, 1994), the bridge appears to be in excellent condition. The tests on bridge #270 were done with a truck that was one third the weight of the truck used at Wyebrook. However, the displacements for bridge #270 were much larger than the displacements at Wyebrook. At the crown of the arch, the maximum displacements were three times as large. They were three times as large at the walls, and the cracks opened five to ten times as wide. Rehabilitation was recommended for bridge #270, of course, but this shows that the Wyebrook bridge is in excellent condition. Table 2 compares a few critical values.

Table 2: Comparison of Displacement Data

Full Truck Weights	Wyebrook Bridge 69,600 lbs.			Bridge #270 33,150 lbs.		
Displacements (in. x 10^{-4})	Inst. #	Max	Final	Inst.#	Max	Final
Crack	9	8	1	12	88	33
Spandrel Wall	2	21	15	13	30	10

Regression Analysis

The quality and consistency of the data from the present testing program may not be good enough to draw certain conclusions about the precise loading capacity of the bridge. However, some linearity can be observed from the more reliable instruments.

The linear regression analysis for LVDT2, LVDT3, LVDT5, and LVDT10 was done using the data from the last three trials of tests beginning with the letters eru, hru, and fru. These instruments were located on the "right" side of the bridge, so the "r" tests are the ones that show the most significant results. The analysis for LVDT6 and LVDT9 used the data from elu, hlu, and flu tests because the instruments were located on the "left" side of the bridge. The data from LVDT1, LVDT4, LVDT7, and LVDT8 were deemed unreliable, and therefore were not analyzed.

With the exception of LVDT5, all of the tests show a clearly linear relationship between truck weight and displacement. There is no reliable evidence of non-linear behavior. The non-linearity exhibited by LVDT5 is probably due to bad data, rather than a weakness in the bridge. This conclusion can be drawn because of the singular data point that seems to cause the problem.

CONCLUSIONS AND RECOMMENDATIONS

Based on the tests carried out on April 12, 1996, it can be concluded that the rehabilitation of the Wyebrook bridge was successful. The engineered fill and the transverse cables seem to have alleviated the earth pressure on the spandrel walls, and the arches are structurally sound. The observed displacements were minor at all of the instrument locations, and we found no real evidence of residual displacements, even with the fully loaded truck. Most importantly, no non-linear behavior was observed in the displacement data, which leads to the conclusion that one third of the failure load of the bridge was not reached (Hendry, 1985). Therefore, it is safe to conclude that little or no damage was done by a truck weighing 35 tons. Considering a safety factor of approximately 2.0, it is recommended that the bridge remain posted for a weight limit of 15 tons to avoid damage to the structure.

Although this report has shown that the bridge is currently structurally sound, this type of testing should be repeated periodically to monitor the performance of the structure over time.

Lafayette College
Alumni Hall of Engineering
Easton, PA 18042

Faculty Advisor:

Dr. Roger Ruggles

The Third World is facing a staggering food and water crisis in the approaching decades. Population trends and lack of food supplies call for research in engineering solutions to these problems. One engineering solution is the use of irrigation in developing countries to increase crop production. Problems arise however if irrigation is inappropriate for use in a country. The purpose of this study is to determine the economic, demographic, and geographic variables that may influence irrigation in a country. Regression analyses are made on 11 different variables from 30 countries in Africa. The final result is a model showing irrigated area as a function of population, cultivated surface area, percent labor force in agriculture, annual rainfall, and irrigation potential. This information may be useful in evaluation of irrigation potential of a developing country.

INTRODUCTION

Background

Despite past efforts to assist the shortages in lesser developed countries (LDCs), the Third World is facing a staggering food and water crisis in the approaching decades. Current research has found that the world's population of 5.3 billion will increase to 9 billion over the next 40 years with approximately 95% of the growth occurring in LDCs. This means that the food requirements of the already malnourished nations will more than double in the next 30 years (Pereira, Gilley, and Jensen 172). It is crucial that research continue in the area of applying appropriate technology to developing countries in order to bring these billions of people their basic necessities.

The realization of this need for appropriate engineering solutions to this crisis led to a workshop held in Vimeiro, Portugal during March of 1994. Entitled "Sustainability of Irrigated Agriculture (Sustainability of Water Resources Utilization in Agriculture)," the workshop focused on the evaluation of irrigated systems in agriculture and prioritizing what research on irrigation is needed to meet the forthcoming challenge of population growth (Pereira, Gilley, and Jensen 175). The participants of this workshop consisted of the leading irrigation authorities in the world. This prestigious workshop made the point that irrigation is one form of modern technology that will be important in ameliorating the LDCs' capability of feeding their population.

Irrigation is the strategic redistribution of water to create arable land in normally arid areas. There are any different types of irrigation that vary in effectiveness depending on the conditions of an area. For example, dry land areas in proximity to a large source of water supply may afford to use surface flooding or a furrow form of irrigation. On the other hand, areas with limited water or sensitive crops may require a more precise use of water in the form of drip irrigation. In addition, between these two extreme forms of irrigation there is a variety of other methods to choose from.

With the wide range of irrigation methods applicable to different land conditions, it may seem logical to assume that irrigation should be implemented in all developing countries to increase the food production. On the contrary, there are likely to be economic, demographic, and geographic factors that suppress the ability of a country to irrigate. Determining these variables and how they affect irrigation potential could be very useful in the strategic implementation of irrigation to developing countries. If a specific LDC has large magnitudes of variables that are negatively correlated with irrigation, it may be unwise or ineffective to use irrigation as a means to aid in the food crisis in that area. In the same way, finding considerable quantities of variables in a LDC that encourage irrigation means that country has the conditions that are appropriate for irrigation.

Purpose of Study

The purpose of this independent study is to determine the economic, demographic, and geographic factors that govern the amount of irrigation in a developing country. To complete this objective, eleven variables will be compared to the amount of irrigated area in developing countries to see if a correlation exists. Through several regression analyses, the wide range of variables will be narrowed to a few variables that have the greatest correlation with irrigated area. Due to extensive information available by the Food and Agriculture Organization on irrigated area in Africa, the regression analyses will focus on data from the developing countries within this continent.

DESCRIPTION OF RESEARCH

Choice of Variables

With any attempt to determine which independent variables govern the quantity of another variable, it is essential that many independent variables are chosen initially covering the many areas that can potentially influence the dependent variable. The more independent variables at the onset of the study, the more credible the governing independent variables at the conclusion of the study. For this reason, the variables chosen in this study must include representation from the diverse range of economic, demographic, and geographic factors.

After discussions with economic and engineering faculty at Lafayette College, variables that might influence irrigation in a country were chosen for use in the regression analyses. The economic variables chosen were gross domestic product (GDP), quantity of agricultural imports and exports, and rate of inflation. The demographic variables deemed important were population, and percent of labor force in agriculture. The initial geographic variables included total surface area of the country, amount of land cultivated, amount of land cultivable, amount of land that has irrigation potential, and average annual precipitation.

Summary of Data Collected

After choosing a preliminary list of pertinent variables that may influence irrigation, the next step was to collect a sufficient amount of data to run a credible regression analysis. The majority of the data collected on the selected variables was obtained from AQUASTAT, the Food and Agricultural Organization's statistical database for irrigation in African countries located on the World Wide Web (http://recoda.fsagx.ac.be:80/faoweb/waicent/faoinfo/agricult/aquastat/aquastat.htm). Where AQUASTAT lacked information, data was found in the CIA World Fact Book also located on the WWW (http://www.itaiep.doc.gov/eebic/econcomm/cia/html).

In summary, data for all of the variables were obtained for a total of 30 African countries. The data collected for Senegal and Sudan is given in Table 1 as an example.

Table 1: Data Collected for Senegal and Sudan

Variable	Senegal	Sudan
Irrigated Area (ha)	141,400	1,946,000
Population (in 1994)	8,102,000	27,361,000
Total Surface Area (ha)	19,672,000	250,581,000
Cultivable Area (ha)	3,782,000	105,000,000
Cultivated Area (ha)	2,300,000	7,600,000
Exports ($ Thousands)	153,393	418,931
Imports ($ Thousands)	385,613	295,948
% Labor Force in Agriculture	77	80
GDP ($ Billions)	12.3	23.7
Inflation Rate (%)	-1.8	112
Annual Precipitation (km^3)	146	1092.6
Irrigation Potential (ha)	400,000	4,842,600

Discussion of Regression Analyses

In this study, the independent variables are those that were predicted to influence the dependent variable of irrigated area. In order to obtain multiple regression analyses quickly, a statistical computer application, Minitab, was used to develop the best model. Minitab has an option of running several regression analyses involving combinations of different variables to develop the best model based on R^2. The results of these analyses are given in Table 2. The variables in the heading of the table are defined as population (P), total surface area (TA), cultivated area (CDA), exports (EXP), imports (IMP), % labor force in agriculture (L), gross domestic product (GDP), inflation rate (INF), annual precipitation (R), and irrigation potential (IP). The variables marked with an "X" in a particular regression analysis were included in that analysis and resulted in the R^2 value given.

Table 2: Regression Analysis Results

Analysis	R^2	P	TA	CA	CDA	EXP	IMP	L	GDP	INF	R	IP
1	.346						X					
2	.334				X							
3	.576						X			X		
4	.559						X					X
5	.628							X			X	X
6	.625						X			X		X
7	.715	X			X			X				X
8	.698			X				X			X	X
9	.755	X			X			X			X	X
10	.749			X		X		X			X	X

21	.793	X	X	X	X	X	X	X	X	X	X	X

What is informative about the results given in Table 2 is that the eleven-variable model (R^2=.793) is not significantly better than the five-variable model in the ninth analysis (R^2=.755). This implies that amongst the variables chosen in this study, the most important variables are the five given in the ninth analysis. These five variables are population, cultivated area, percent of labor force in agriculture, annual precipitation, and irrigation potential. The final model relating these factors to irrigated area is given in Eq. 1.

$$I = 518440 - 0.0216\,P + 0.113\,CDA - 7190\,L - 211\,R + 0.298\,IP \qquad (1)$$

A measure of the accuracy of this model in estimating the influence of these five variables is given in Figure 1. In this figure, the y axis are the values for irrigated area after inputting the data used for the regression analysis into Eq. 1. The x axis is the actual value of irrigated area in the data. While there seems to be a few points where the model was relatively inaccurate in judging the actual irrigated area, the model does appear to show most of the points following the line of a perfect model. It may be concluded from this that these five variables have governing correlations with irrigated area in this study.

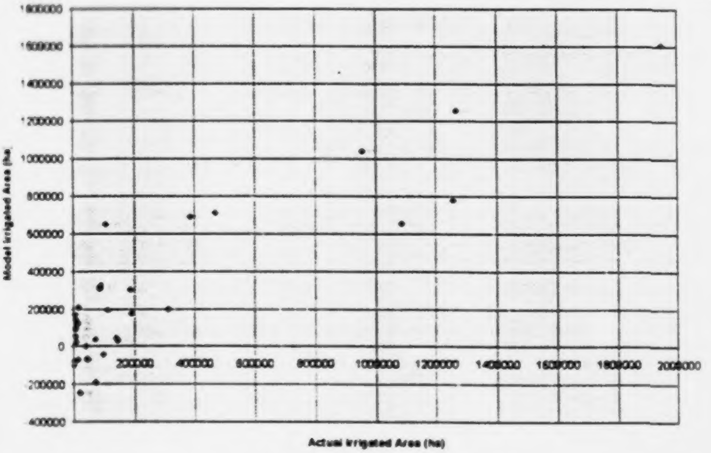

Figure 1: 5-Variable Model vs. Actual Irrigated Area

CONCLUSIONS

Reasons for Positive and Negative Correlations of Variables

As concluded in the above discussion of the research, the five variables found in this study to most govern the amount of irrigated area in African countries are population, cultivated area, percent of labor force in agriculture, annual precipitation, and surface area with potential for irrigation. Having established the correlations between irrigated area and these variables indicated in Eq. 1, it is now pertinent to discuss possible explanations for these correlations. The actual reasons for the positive or negative correlation of the five variables with the amount of irrigated area in a country are beyond the scope of this study. However, simple speculation may explain the feasibility of these correlations.

The negative correlation of P and L may be due to the fact that the more people there are in a country, the more people will be working in agriculture. This is especially the case in a country where there is a large percentage of the labor force working in agriculture. The more people working on an agricultural project means there is less of a need for an automated irrigation system because there will be more hands to properly water and tend to the crops manually.

The negative correlation of the R may be speculated simply by the relationship that the more rainfall there is, the less need there is for an irrigation system to bring water to dry soil. Contrary to arid areas, countries that have high precipitation will have an adequate water supply and will not need some form of forced water supply.

The positive correlation between CDA and I is illustrated by the common sense that the more area cultivated, the more of a need there is for irrigation. As the demand for cultivated area increases, the ratio of total agricultural workers available to cultivated area decreases. The ratio of water supply from precipitation to cultivated area decreases as well. Hence, there is more of a need to direct water to agricultural sites through irrigation because of the shortage of water and manual labor.

IP is positively correlated to I because the more potential for irrigation there is, it is to be expected that a country will utilize that potential. If crops are in a location that can be more easily irrigated, it would be easier and more efficient to irrigate those crops.

Usefulness of Information

Having found five specific variables that potentially influence irrigation amounts, the objective of this research has been fulfilled. The results of this research will be useful in determining the appropriateness of irrigation in the approaching food and water crisis.

The best use for the five most influencing variables is in analyzing whether irrigation is practical for use in a developing country. Before using irrigation as a means of relieving famine in a LDC, it may be useful to determine if the variables that positively correlate with irrigated area are prominent in that country. If the negatively correlated variables are more significant, perhaps a different solution instead of irrigation needs to be developed for that area.

Another result of this research is the realization that a variety of variables can be correlated significantly to the amount of existing irrigation in a country. This indicates that more research should be done on other variables that could influence irrigation. It seems from this study that such research could be very helpful in ameliorating the food and water crisis predicted for the approaching decades.

Asheville, North Carolina 28804-3299

Faculty Advisor:

Dr. Charles Bennett

The Motorola 68HC11 based Mini Board is a single-board computer developed for use in small, mobile robot control. It is readily available and an economical choice for hobby, educational, and introductory robotics. Although limited by its small memory size (2K of EEPROM), its computing capabilities can be substantially increased by parallel processing. The 68HC11 incorporates a mechanism to network together multiple Mini Boards with the Serial Peripheral Interface (SPI). This research explored the issues of creating a generic, robust and reliable networking protocol for the 68HC11. Significant factors considered in the creation of this protocol are write collisions, master/slave selection, compiled code size, and network contention.

INTRODUCTION

Influenced by MIT's 6.270 Robot Design course, this research began with a project to build a small, mobile robot using the Mini Board from MIT. The Mini Board is a single-board computer developed for use in small, autonomous mobile robot control. It is readily available and an economical choice for hobby, educational, and introductory robotics.[1] It is built around the Motorola microcontroller, MCU 68HC811E2, part of the 68HC11 family and has support for motors, analog and digital inputs, and outputs. However, the Mini Board's capabilities are limited by its available memory, having only 2K (2,048) bytes of memory (EEPROM, Electrically Erasable Programmable Read Only Memory) and allowing only approximately 100 lines of 'C' code using the specially designed 'C' compiler. However the microcontroller does provide networking functionality that may be utilized to overcome the memory limitation.

The 68HC11 family of microcontrollers incorporates the SPI (Serial Peripheral Interface) subsystem, "an independent serial communications subsystem, [which] allows the MCU to communicate synchronously with peripheral devices ... [and] is also capable of inter-processor communication in a multiple master system."[2] Two of the Mini Board's RJ-11 connections ("telephone jacks") allow multiple Mini Boards or other devices to communicate. Using this system, it is possible to connect multiple Mini Boards in a network. However, Motorola does not provide a generic networking protocol. Dr. Fred Martin, designer of the Mini Board, included hardware support for the networking functionality, but he left the development of a generic networking protocol as a "challenge."[1]

Using this networking capability, it is possible to increase the available memory by creating a parallel processing system. Thus, while the individual Mini Boards have only a small amount of memory, the system has a larger amount, dependent upon its size. Another benefit of this approach is that a robotic system lends itself naturally to a "divide and conquer" parallel processing system (i.e. problems are divided into smaller units which single processors complete). Many different functions of a robot, such as different sensing, movement, and their fusion are inherently parallel and can be divided into smaller units.

Consequently the purpose of this research is to explore the issues of developing a generic, robust, and reliable networking protocol for the Motorola 68HC811.

METHODOLOGY

This research began by gaining an understanding of the SPI subsystem through readings of the technical literature, including Motorola's M68HC11 Reference Manual. As there is a large body of research in data networking and telecommunications, pertinent literature was read to develop an understanding of existing protocols. The next step was to demonstrate that two Mini Boards could communicate in some fashion. If they could not communicate, as the simplest case, then creating a network would be impossible. Lastly, after deciding what issues needed to be addressed to create the protocol, a theoretical model was developed, implemented and tested.

RESULTS

Obstacles

The first step in creating a system is to understand the obstacles that must be overcome. The following are the five obstacles that were discovered:

The first obstacle was the *limited memory available*. If the protocol required a large amount of memory, then it is useless, as there is no memory left to implement other functions. Therefore, an arbitrary limit of one-half (.5) of the available memory was established for the protocol. Since there is a total of 2,048 bytes of memory, this yielded 1024 bytes for the compiled protocol. This was a reasonable amount of memory in which to implement the protocol that left a significant amount of memory for other functions.

The second obstacle was the *physical topologies available*. Every Mini Board can be connected to a maximum of two others (there is no one "bus" that all can be connected to). Therefore the available physical topologies were severely limited.

The third obstacle concerned *which Mini Board controls the transfer of data*. Since transfers occur only at the request of a master, slaves have no control over when data will be sent. If a slave is not ready for a transfer, the master has no means to detect that until a transfer has been attempted. Conversely, if a slave has data to transfer, it must wait until the master initiates the transfer. This could result in problems such as a master spending a significant amount of time "polling" a slave by repeatedly attempting transfers and data not being sent within a reasonable amount of time (i.e. "old data").

The fourth obstacle involved the *single master constraint* There can only be one master among Mini Boards connected within two "steps." In Figure 1, only Mini Board C can be configured as a master. If Mini Board A is configured as a master and attempts to transfer data (to B) while C is transferring data (to B), then a "multiple master bus contention error" occurs and the system fails. To ensure that this does not occur, only Mini Board C in the figure may be in master mode.

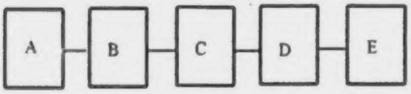

Figure 1 Master v. Slave Mode

The last obstacle was the *data transfer "size."* Due to hardware limitations, only 8 bits can be transferred at one time from master to slave and vice versa. This severely limits the existing networking protocols, as many require a large number of bits for "wrappers", that include information such as the destination address, data content type, source address, and error checking codes.

Physical Topology

The physical topology that most adequately corresponded with the physical requirements of the Mini Board was the ring. Figure 2 shows an illustration of a ring. A ring is a "network topology in widespread use for the interconnection of communities of digital devices distributed over a localized area... each device is connected to its nearest neighbor until all the devices are connected in the form of a closed loop or ring."[1] As Mini Boards can be connected directly to a maximum of two others, the ring topology, which connects each device to two others, seemed a natural choice.

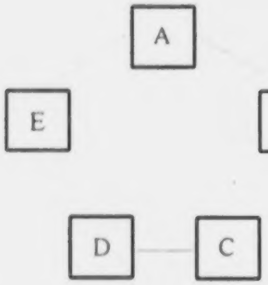

Figure 2 Ring Topology

Network Initialization

Since only Mini Boards configured as masters can begin a data transfer, only by becoming a master and attempting to transfer data to a slave (i.e. polling) can it be determined if the slave is ready for data. However, if all Mini Boards did this upon powering on to assure that the network was functioning, there would be a high probability that a large number of bus contention errors would occur. Thus, some way to initialize the network needed to be developed so that no bus contention errors would occur. The algorithm devised to initialize the network is as follows:

1. A Mini Board designated as the "Master" (similar in some ways to the "monitor" of a token ring network) attempts to transmit its ID number to its successor.

2. The Mini Board designated as the successor of the Master, upon receipt of data, then transmits its ID to its successor. (This step in designating the second Mini Board was needed because of the bi-directionality of the links.)
3. From this point, each Mini Board, upon receipt of the ID of its predecessor, sends its ID to its successor. (Note, that the ID of each Mini Board is its predecessor's ID incremented by one. Therefore, a Mini Board must only transmit its ID when it receives a lower valued ID.)

4. When the Master receives the ID of its predecessor, it transmits a NETWORK_UP packet, signaling that the network is functioning.

5. When a Mini Board receives the NETWORK_UP packet, it sends the packet to its successor, then defaults to slave mode and enables its SPI interrupt. When the Master receives the NETWORK_UP packet, it sends out the CONTROL_TOKEN, then defaults to slave mode and enables its SPI interrupt. At this point, the network initialization is complete.

To guard against bus contention errors, the default of all the Mini Boards in the network is slave mode. When it is necessary that data be sent, the Mini Board changes to master mode, sends the data, and then immediately reverts to slave mode. This is discussed more fully in the next section.

Data Transfers/Network Operation

The data transmission is controlled by the use of a control token. The control token is transmitted from one Mini Board to another until it is received by a Mini Board (source) wishing to send data. It then sends a frame with the destination ID, followed by the data sent in data packets (of 8-bit length as required by the SPI subsystem). When all frames have been sent, an end-of-transmission frame is transmitted. The source then transmits the control token. Note that during these transfers, each Mini Board received data as a slave, parsed the data and, if necessary, changed to master mode to send the data, after which changing back to slave mode. Thus the possibility of bus contention errors has been eliminated.

CONCLUSIONS/SUMMARY

In developing this protocol, all the obstacles outlined earlier were circumvented. Overcoming the limited amount of memory available proved to be difficult. There were many features that would have been useful additions, however their implementation necessitated more memory than was feasible. Features such as data validity, error checking, and the retransmission of corrupted packets are useful, but not required and thus were not included in the final protocol. Although the number of physical topologies available was limited, the hardware configuration lended itself naturally to the ring topology. The single master constraint and the transfer of data being controlled solely by a master required the unusual technique of Mini Boards defaulting to slave mode. However, this sufficiently thwarted bus contention errors resulting from multiple masters, required to both initialize and send data around the network. The data transfer size generated more network traffic than would have been necessary given a larger packet size. Since there is no means to deal with corrupted packets, the greater the number of packets, the greater the probability that the data will be corrupted. However, as discussed earlier, because of the physical transfer medium, packet errors are at a minimum.

The protocol has been implemented and tested on an experimental network of two Mini Boards. The protocol implementation functions as expected. Due to the nonavailability of more Mini Boards, the protocol has not been tested on a larger network.

Ideal Case Modeling of Optical Preamplifer Receivers at the 10Gb/s Data Rate

Deborah S. Hart

Department of Physics
University of North Carolina at Asheville
One University Heights
Asheville, NC 28804-3299

Faculty Advisor:

Y. K. Park, Lucent Technologies, Lightwave Subsystems

It is important when designing optical preamplifier receivers (OPRs) to define the critical parameters and predict performance based on these parameters. An ideal case simulation can give important preliminary information to direct research and development. In this research, a simplified approximation relating effective gain and receiver noise in the ideal case was developed and its significance as it relates to receiver sensitivity was investigated. As a result, receiver noise was shown to dominate the low gain regime, while spontaneous noise factor and input coupling efficiency dominate the high gain regime. A design tool was employed which used symbolic math programming to model the important design parameters. Simulation results indicate that the receiver sensitivity penalties due to the extinction ratio (the ratio of the signal level on the ones to the signal level on the zeros) and the optical bandwidth of the OPR are coupled, all other parameters investigated are independent of each other.

INTRODUCTION

The advent of wavelength division multiplexed (WDM) all-optical networks is revolutionizing the telecommunications industry. Especially significant to the development of this new technology are the erbium-doped fiber amplifiers (EDFAs) which operate in the 1500 nm telecommunications window. EDFA-based OPRs can be used to overcome signal losses associated with long transmission distances and high data rates.

The purpose of the OPR is to improve the receiver sensitivity while maintaining a bit error rate (BER) of 10^{-9} (one error for every 10^9 bits transmitted). In wavelength multiplexed systems, the OPR can compensate for splitting losses and amplify the signal before regeneration. While amplifying the signal increases the signal to noise ratio (SNR), the use of optical amplifiers introduces amplified spontaneous emission noise (ASE) into the signal path.[1] If the SNR is degraded there is a corresponding degradation of the receiver sensitivity. This research investigated the receiver sensitivity penalties associated with major OPR design parameters and developed a simplified equation for modeling the ideal case receiver sensitivity.

OVERVIEW OF CRITICAL PARAMETERS

The theoretical model has been described by the author and others in the literature[2-4] and will not be covered in this paper. Table 1 lists the parameters investigated along with their ideal and experimentally measured values. Employing the design tool, the incurred receiver sensitivity penalties are calculated cumulatively in the order listed. Optical bandwidth (B_o) is the bandwidth of the optical filter in the OPR. The optical filter serves to eliminate some of the ASE noise produced by the EDFA; however, it is important to characterize how it affects receiver sensitivity because a WDM system will require a wider bandwidth than a single wavelength system. Extinction ratio (ϵ) is the ratio of the dB level of the ones to the dB level of the zeroes. It becomes difficult to maintain high extinction ratio at high data rates; therefore, the trend towards higher data rates make it imperative to characterize the effect of extinction ratio on receiver sensitivity. Input coupling loss (η_i)

includes all losses incurred when coupling the signal from the fiber into the EDFA portion of the OPR. Noise figure (NF) is the internal noise figure which is dependent upon the ASE power from the amplifier. Electrical bandwidth (B_e) is the filter bandwidth of the receiver portion of the OPR. Gain is the internal gain of the EDFA. . Unaccountable is the difference between the experimentally measured receiver sensitivity and the calculated sensitivity. The receiver thermal noise for all the simulations is assumed to be 13 pA/sqrtHz.

Table 1

Sources of the Receiver Sensitivity Penalty and Their Penalty Values for a 10Gb/s Prototype Optical Preamplifier Receiver

Penalty Source	Ideal Value	Experimentally measured value	Incurred penalty (dB)
Optical bandwidth (B_o)	10 GHz	42 Ghz	0.8
Extinction ratio (ϵ)	> 30 dB	14 dB	1.0
Input coupling (η_i)	1	0.8	1.0
Amplifier noise figure (NF)	3 dB	3.7 dB	0.7
Electrical bandwidth(B_e)	5 GHz	7 GHz	1.3
Gain for $I_s = 13\frac{pA}{\sqrt{Hz}}$	> 50 dB	33.0 dB	0.0
			Total penalty = 4.8 dB
Unaccountable	0	1.0 dB	
Receiver sensitivity for 10^{-9} BER	-42.6 dBm	-36.8 dBm	

IMPROVEMENT OF DESIGN TOOL

The design tool based on the theoretical model was created using Mathematica 2.2, a symbolic math programming environment. This allows significant design parameters to be varied so that the effects on performance could be studied. The design tool has been improved by implementing an algorithm based on the work of Paul Moser[3]. The factors α_s, γ_{ss}, δ, γ_1, γ_0, are parameterization factors based on the design parameters. The theoretical model[2] can be expressed as a single modeling equation based on a BER of 10^{-9} using these parameterization factors. This yields the following second order equation which can be solved for P_l, receiver sensitivity:

$$\alpha_s^2P_l^2-2\alpha_s\gamma_{ss}P_l+(\gamma_{ss}^2-4\delta\alpha_s-4\gamma_1\gamma_0)=0 \qquad (1)$$

Equation 1 can be solved for P_l, the receiver sensitivity.

This algorithm greatly improves the computing speed of the design tool.

INTERACTION BETWEEN PARAMETERS

It should be noted that in Table 1 the incurred penalties are calculated cumulatively in the order recorded in the table. The order in which the penalties are calculated was found to be independent for all parameters except optical bandwidth (B_o) and extinction ratio (ϵ). In addition, when all the parameters are varied independently, slightly higher values are obtained for optical bandwidth and extinction ratio penalties. These values are listed in Tables 2 and 3.

Table 2

Interaction of B_o and ϵ

Order in which calculated	Parameter	Incurred penalty (cumulatively calculated)	Incurred penalty (independently calculated)
1	Optical bandwidth (B_o)	0.8	1.4
2	Extinction ratio (ϵ)	1.0	0.9

Table 3

Interaction of B_o and ϵ

Order in which calculated	Parameter	Incurred penalty (cumulatively calculated)	Incurred penalty (independently calculated)
1	Extinction ratio (ϵ)	1.4	0.9
2	Optical bandwidth (B_o)	0.4	1.4

The results show that when the two parameters are taken together the overall cumulative penalty remains the same but their individual values varied. When these parameters are calculated independently their sum is 0.5 dB higher.

DEVELOPMENT OF IDEAL CASE EQUATION

Assume the following:

1) extinction ratio (ϵ) is very large,

2) Spontaneous-spontaneous beat noise and shot noise are negligible,

3) effective gain G_{eff} is the product of intrinsic amplifier gain and input and output coupling efficiencies.

When these assumptions are substituted into the algorithm used for the simulation[3], after some calculations a simplified approximation for the receiver sensitivity P_l can be made.

$$P_l = 6\frac{\sqrt{N_e}}{G_{eff}} + 72 B_e h\nu \frac{N_{sp}}{\eta_i} \qquad (2)$$

where N_c is the receiver circuit noise, hv is the photon energy of the signal, and N_{sp} is the amplifier spontaneous emission factor.

It can be seen from Figure 1 that this simplified approximation closely follows the simulation results up to ~25 dB. At gains above 25 dB there is ~0.5 dB difference.

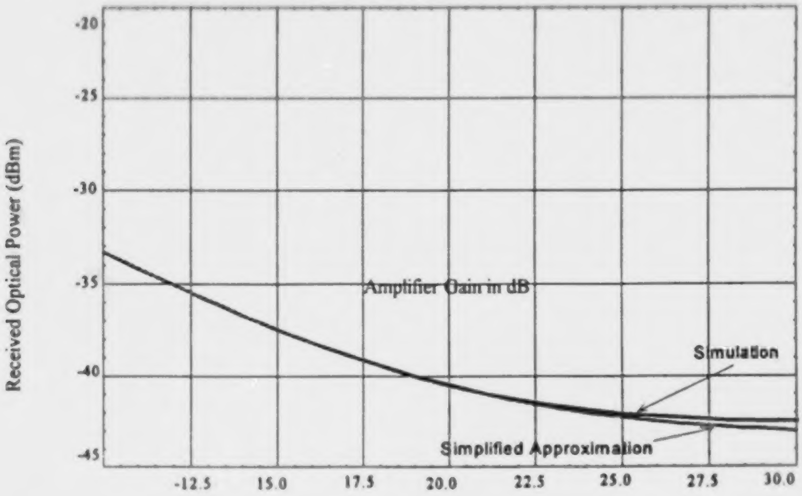

Figure 1: Comparison of Simulation to Simplified Approximation in the Ideal Case

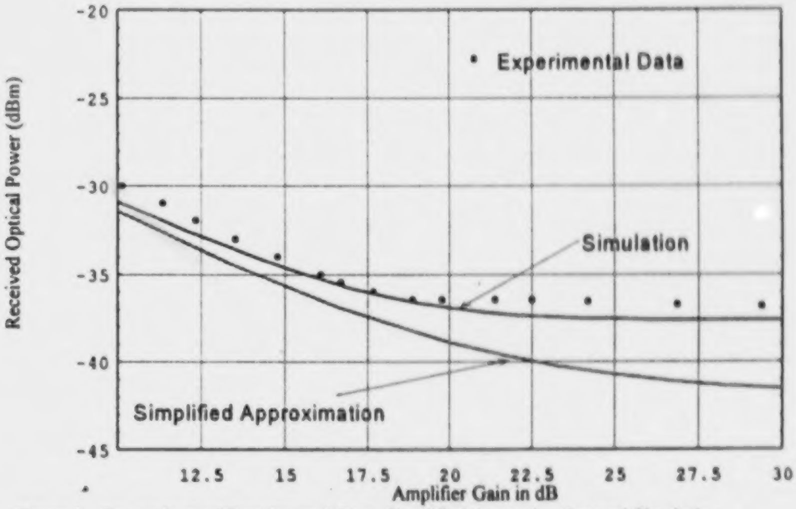

Figure 2: Comparison of Experimental Data, Simplified Approximation and Simulation

COMPARISON WITH EXPERIMENTAL RESULTS

It can be seen from Figure 2 that the simplified approximation does not model the experimental results (obtained from a prototype OPR) well. This is because it was developed on the assumption of high extinction ratio which reduces noise contributions on the zeros, and on the assumption that the spontaneous-spontaneous beat noise is negligible. Therefore, its usefulness is limited to modeling the ideal limit rather than practical design limitations. The simulation remains within 1 dB of the experimental data throughout both gain regimes and is shown to be useful for modeling practical limitations[4].

CONCLUSIONS

The design tool simulation remains within 1 dB of the of the experimental data (obtained using a prototype EDFA-based OPR) throughout both gain regimes (Figure 2). This makes the simulation useful for practical design applications. Further development of the simulation should include ISI (intersymbol interference) contributions to more accurately model the receiver sensitivity.

When employing the simulation, care should be taken in stating the penalties incurred due to optical bandwidth (B_o) and extinction ratio (ϵ) because they are dependent on the order in which they are calculated if calculated cumulatively. These parameters also have slightly higher values when calculated independently. The independent calculation is of limited practical use, however, since in a real system all parameters will be less than ideal.

Analysis of Eq. 2 clearly shows that there are two gain regimes. In the low gain regime, receiver circuit noise will dominate and there is a linear increase in receiver sensitivity as gain increases (~1 dB increase in receiver sensitivity for 1 dB increase in gain). In the high gain regime, the first term will become negligible and the noise floor will be reached (no further increase in receiver sensitivity). The noise floor will be primarily dependent on N_{sp}, the amplifier spontaneous emission factor and η_{in}, the input coupling efficiency. In Figure 1 it can be seen that the parameters in Eq. 2 account for the general shape of the receiver sensitivity curve. In Figure 2 the remaining parameters incur penalties which serve to shift the curve towards overall degraded sensitivities. While this approximation has limited use in practical design, it can quickly yield the ideal limit allowing the designer to easily compare prototypes.

Richard R. Schultz

Ultrasound medical images are inherently noisy, since acoustic waves are reflected back to the sensor rather erratically after striking tissue and bone. Several powerful nonlinear image processing techniques have been applied to digital ultrasound imagery to both filter the noise and enhance the data. First, two morphological filtering operations, namely the opening and closing, have been used to remove noise while preserving important image features such as edges. Visually, the quality of the digital ultrasound images is improved, and analysis of the filtered biomedical imagery becomes easier. Next, a Bayesian enhancement technique was applied to the digital ultrasound image to increase spatial resolution. The enhanced image appears to have a higher resolution than the same image enhanced using bilinear and cubic B-spline interpolation. Finally, a Bayesian multiframe resolution enhancement technique has been applied to a digital ultrasound image sequence, in which several frames are integrated to compute a high-resolution video still image. All three nonlinear filtering and enhancement techniques will be compared visually in this paper.

INTRODUCTION

Ultrasound medical images are inherently noisy, since acoustic waves are reflected back to the sensor rather erratically after striking tissue and bone. In an effort to obtain an enhanced ultrasound image, several nonlinear filtering techniques will be employed, including morphological filtering (Gonzalez, R. C. and Woods, R. E., 1992), Bayesian single frame enhancement (Schultz, R. R. and Stevenson, R. L., 1994), and Bayesian multiframe resolution enhancement (Schultz, R. R. and Stevenson, R. L., 1996).

An ultrasound image of a dog's heart is shown in Figure 1. This image is a frame extracted from a short digital image sequence of a dog's beating heart. Initially, the most common image enhancement techniques, bilinear and cubic B-spline interpolation (Schultz, R. R. and Stevenson, R. L., 1994), will be applied to this data. Both methods expand the original $N \times N$ pixel image by first interpolating each of the N rows by a factor of q, and then by expanding each of the resulting qN columns by the same factor. Figures 2 and 3 contain more precise details than the original ultrasound image, and these two images will be used as benchmarks of comparison for the nonlinear filtering and enhancement techniques. Each of the filtering and enhancement techniques proposed in this paper will be applied to either the single frame or to multiple video frames. A visual comparison of the results will take place to determine the efficacy of each method for the purpose of image analysis.

MORPHOLOGICAL FILTERING

Set theory is the basis of morphological filtering. These sets represent the structure, or morphology, of objects in an image. Dilation and erosion are the two basic morphological operations (Gonzalez, R. C. and Woods, R. E., 1992), and they will be used to perform a morphological opening and closing on the grayscale digital ultrasound image.

Morphological Dilation and Erosion

Consider binary images containing black and white pixel values with sets A and B contained within Z^2. The dilation of set A by the structuring element B is defined as

$$A \oplus B = \left\{ x \,\middle|\, (B)_x \cap A \neq \varnothing \right\}. \tag{1}$$

The structuring element B, in this case a 3 x 3 digital square, is translated throughout the binary image pixel-by-pixel. If a single point contained within set A is present within the structuring element at point x, the output image turns on at that point. The resulting output image contains an expanded, or "dilated," version of the original set A. For grayscale image data, the result is a brighter image than the original, since each image pixel intensity value is increased by a 6-point structuring element representing a digital sphere. This is certainly evident in the morphological dilation of the grayscale ultrasound image shown in Figure 4.

Again, for binary images, the erosion of set A by the structuring element B is defined as

$$A \otimes B = \left\{ x \,\middle|\, (B)_x \subseteq A \right\}. \tag{2}$$

The 3 x 3 square structuring element is once again translated throughout the binary image pixel-by-pixel. In this case, the output image pixel at location x is not turned on unless the entire structuring element is contained within A. The final output image contains a smaller, or "eroded," version of the original set A. For grayscale image data, the result is a darker image than the original, since each image pixel intensity value is decreased by the 6-point spherical structuring element. Morphological erosion of the grayscale ultrasound image can be seen in Figure 5.

Morphological Opening and Closing

A morphological opening is simply an erosion followed by a dilation, with the nonlinear filtering operation defined as

$$A \circ B = (A \otimes B) \oplus B. \tag{3}$$

The morphological opening operation filters a grayscale image by first eroding the intensity values and then filling in gaps by dilating the remaining data. Figure 6 shows the results of an opening operation applied to the grayscale ultrasound image.

A morphological closing consists of a dilation followed by an erosion, and it is defined as

$$A \bullet B = (A \oplus B) \otimes B. \tag{4}$$

A closing tends to smooth sections of the image by first filling in gaps between intensity values and then eroding away the excess data. See Figure 7 for an example of a morphological closing applied to the grayscale ultrasound image.

BAYESIAN IMAGE ENHANCEMENT TECHNIQUES

Image enhancement can be posed as the following estimation problem: given the N x N pixel low-resolution image **y**, estimate the qN x qN pixel unknown high-resolution image **z**. Bayesian maximum *a posteriori* (MAP) estimation is a statistical technique based on Bayes' theorem which can accurately compute the high-resolution image. The estimate is defined as

$$\hat{\mathbf{z}} = \arg\max_{\mathbf{z}} \left\{ \log \Pr(\mathbf{y} | \mathbf{z}) + \log \Pr(\mathbf{z}) \right\}, \tag{5}$$

where Pr(**y**|**z**) is the probability density function of the noise, and Pr(**z**) is the prior probability density of the image data. First, the Bayesian single frame enhancement algorithm will be described, and then the algorithm will be extended to include multiple image sequence frames.

Bayesian Single Frame Image Enhancement

In our subsampling model, the average of $q \times q$ high-resolution pixels is assumed to be the value of a single low-resolution pixel. This image observation model is given as

$$\mathbf{y} = \mathbf{A}\mathbf{z}, \tag{6}$$

where **A** is known as the subsampling matrix. Each row of **A** averages a block of pixels from the $qN \times qN$ pixel image **z**, resulting in a single intensity value within the $N \times N$ pixel image **y**. No noise has been incorporated into the image observation model, since the intent is to expand the image without smoothing. Assuming a Huber-Markov random field model (Schultz, R. R. and Stevenson, R. L., 1994) for the image data, the Bayesian estimate is given as

$$\hat{\mathbf{z}} = \arg \min_{\mathbf{z} \in Z} \left\{ \sum_{m,n=1}^{qN} \sum_{p=1}^{4} \rho_{\alpha}\left(\mathbf{d}^{t}_{m,n,p}\mathbf{z}\right) \right\}. \tag{7}$$

In this optimization problem, the estimate must belong to the constraint set $Z = \{\mathbf{z} \mid \mathbf{y} = \mathbf{A}\mathbf{z}\}$. Four second-order differences are used as edge detectors at each image point, and these values are arguments of the Huber edge penalty function, $\rho_{\alpha}(x)$, which preserves discontinuities. Since the function to be minimized is convex, the gradient projection algorithm (Schultz, R. R. and Stevenson, R. L., 1994) is used to efficiently compute the unique image estimate. Figure 8 shows the ultrasound image enhanced using the Bayesian single frame estimation technique.

Bayesian Multiframe Resolution Enhancement

If a short digital image sequence is available, it may be possible to further enhance the image data by integrating multiple frames. Object motion between frames can be utilized to estimate a high-resolution video still (HRVS) image which is visually improved over the Bayesian single frame estimate (Schultz, R. R. and Stevenson, R. L., 1996). The unknown high-resolution image $\mathbf{z}^{(k)}$ is to be estimated in this case from not only the low-resolution center frame of the image sequence $\mathbf{y}^{(k)}$, but also the surrounding low-resolution frames $\mathbf{y}^{(k-1)}$ and $\mathbf{y}^{(k+1)}$. For the center frame of the video sequence, the image observation model $\mathbf{y}^{(k)} = \mathbf{A}^{(k,k)}\mathbf{z}^{(k)}$ is identical to the single frame model in equation (6). The other low-resolution frames within the sequence should appear similar to the center frame, but with the objects moved slightly with respect to the center frame. An observation model used to accommodate for this motion is given as

$$\mathbf{y}^{(l)} = \tilde{\mathbf{A}}^{(l,k)}\mathbf{z}^{(k)} + \mathbf{n}^{(l,k)}, \quad l \neq k. \tag{8}$$

The motion-compensated subsampling matrix incorporates subpixel-resolution motion vectors that have been calculated between frames $\mathbf{y}^{(l)}$ and $\mathbf{y}^{(k)}$, with the error in the motion estimates represented by a Gaussian-distributed noise vector $\mathbf{n}^{(l,k)}$. Subpixel-resolution motion vectors are estimated by first expanding each low-resolution frame, $\mathbf{y}^{(l)}$ and $\mathbf{y}^{(k)}$, by a factor of q in both directions, and then applying the block matching motion estimation algorithm (Musmann, H. G., Pirsch, P., and Grallert, H.-J., 1985) to the up-sampled data. Once the two motion vector fields have been estimated, the Bayesian multiframe estimate can be computed as

$$\hat{\mathbf{z}}^{(k)} = \arg \min_{\mathbf{z}^{(k)} \in Z} \left\{ \sum_{m,n=1}^{qN} \sum_{p=1}^{4} \rho_{\alpha}\left(\mathbf{d}^{t}_{m,n,p}\mathbf{z}^{(k)}\right) + \lambda \sum_{l=k-1}^{k+1} \left| \mathbf{y}^{(l)} - \tilde{\mathbf{A}}^{(l,k)}\mathbf{z}^{(k)} \right|^{2} \right\}. \tag{9}$$

The new terms which arise in the objective function are due to the error in the motion vector estimates. The gradient projection algorithm is used to minimize the convex objective function, resulting in the high-resolution video still image. Figure 9 shows the HRVS estimate computed from three frames of the digital ultrasound image sequence of the dog's beating heart. Note that in some areas, the resolution is enhanced significantly. However, some artifacts are present due to the inaccurate estimation of motion vectors.

DISCUSSION OF SIMULATION RESULTS

The morphological opening and closing operations tend to remove noise artifacts within the data while leaving the edge structures intact. In the case of medical images, the dilation or erosion of critical information may not be in the best interest of the patient. Thus, morphological filtering may not be appropriate for use in digital radiology, but it can be a useful technique when applied to ultrasonic nondestructive evaluation images (Song, Y.-W. and Udpa, S. S., 1996).

By comparing the image computed through Bayesian single frame enhancement to the images generated by bilinear and cubic B-spline interpolation, it is quite apparent that sharper details are present within the estimate. This added resolution can be important to a radiologist and other medical professionals, since small tumors which cannot be easily detected in the data may become more pronounced in the expanded image.

Bayesian multiframe resolution enhancement is capable of extracting the most detail from the data, since three images from the video sequence are integrated to produce a high-resolution video still image. Provided that the motion vectors can be estimated accurately, the resolution enhancement can be dramatic. In the case of this particular ultrasound image sequence, block matching does not perform well in estimating the motion of the heart valve. These poor motion vectors manifest themselves in the HRVS as ringing artifacts. With the exception of these artifacts, the multiframe enhancement method does generate a high quality image estimate.

CONCLUSION

Several nonlinear filtering and enhancement techniques were applied to digital ultrasound imagery. The morphological opening and closing filtering operations remove much of the noise inherent in ultrasound data, while the Bayesian single frame and multiframe enhancement algorithms extract image details not present in the original frames. Applications arise in the filtering and enhancement of medical and nondestructive evaluation ultrasound images.

Mathematical Modeling of a Fuzzy V-Chip

Daniel J. Landherr

Dr. Marian S. Stachowicz

Recently, President Clinton signed a telecommunications bill into law that required every new television sold in the United States to be equipped with a V-chip. This chip will block inappropriate programming, as determined by the user, from being shown. The V-chip works on a discrete rating system that is sent as a signal over the airwaves. Using fuzzy set theory and fuzzy decision making, we have modeled a V-chip that uses a range of fuzzified values to determine a rating for a show, and uses fuzzy multiperson decision making to determine whether or not a program is blocked by the V-chip.

BACKGROUND

Fuzzy set theory and fuzzy logic are extensions of classical, or crisp, set theory and traditional logic that were developed by Lofti Zadeh in 1965. The difference between fuzzy set theory and classical set theory is that all values between truth and falsehood (one and zero) are used in fuzzy set theory, whereas only truth or falsehood are used in classical set theory. This ambiguity in the level an element belongs to its membership set allows for the linguistic description of variables. For example, in crisp logic, an element in the set "Violent" could only be considered violent (1), or not violent (0). In fuzzy logic, an element can be considered "Violent" to varying degrees, such as somewhat violent (.7), a little bit violent (.2), or just violent to a specific numerical degree between one and zero.

A fuzzy set is consists of elements in a universal space that each have a value of membership in the set. This is why another name for a fuzzy set is the membership set. The value of membership is a number less than or equal to one and greater than zero. The universal space consists of all the elements in all of the membership sets.

Fuzzy decision making is a technique that uses fuzzy sets to describe a decision space and state space, relates these spaces by use of a fuzzy relation to produce a result, and uses a utility function to choose the best alternative. This utility function produces a resultant fuzzy set, and the best alternative is chosen out of the resultant set. Fuzzy decision making is an extension of classical decision making theory using fuzzy sets instead of classical sets. All uses of classical set theory and logic are at the core of fuzzy set theory and logic; classical theory is simply a special case of fuzzy theory.

The current V-chip has three blocking categories. These categories are violent content, sexual content, and mature language. An integer in the range of zero to five is established in each of the categories. Zero corresponds to no offensive content, and five corresponds to the highest level of content. The user of the V-chip decides what level they consider appropriate for each of the three categories. If the show's number rating is higher than the V-chip's number rating for any of the categories, the show is blocked from being shown on the television screen.

Using fuzzy logic to model the V-chip allows the use of linguistic variables to describe the degree of violence, sexual content, or language. Fuzzy logic also describes with uncertainty to allow for differences in a program from episode to episode without re-rating the show. Also, with fuzzy logic, other features that describe educational content or realism can be added to bias the decision to make it more effective.

The most exciting reason to use fuzzy logic in this type of decision making process is that fuzzy sets can be easily aggregated to come up with a final fuzzy set. This allows shows that are educational or informative to offset ratings of content. After aggregating the functions into a final fuzzy set, a user's decision and a show can be compared against each other in order to decide if the show is blocked, and a show rated particularly high in one area has a chance to be a successful decision if it is rated low in other areas, and high in a bias set like educational content. This is related to traditional fuzzy decision making by the use of a decision space (the television programs), state space (the user threshold set), and a fuzzy relation that also serves as utility function to evaluate whether or not a show is blocked.

MATHEMATICAL MODELING

The model of a two-valued V-chip in figure 1 is shown as a special case of fuzzy set theory. Each rating singleton fuzzy set has one element, and each element has a membership rating of one. There are large areas of uncertainty between membership sets that have no membership values in any set. There are different universal spaces for each of the types of content in the V-chip, but the fuzzy sets representing the levels of content are the same.

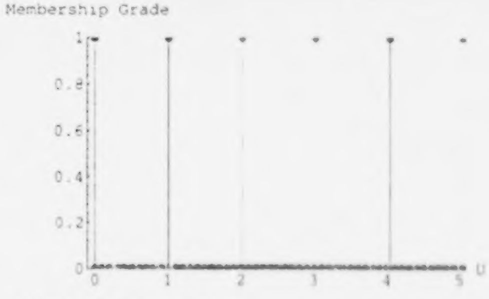

Figure 1: Model of a current V-chip

The current V-chip works in the following manner. Three singleton sets exist for each program, each one is a rating for a type of content. Three singleton sets are determined by the user as a threshold for the level of content, one for each type of content. The rating set for a type of content in a show is compared against the threshold set, for the same type of content, stored in the V-chip. If the rating set has a higher level of content than the threshold set does, for any type of content, the show is blocked. In other words, a decision is made that the show is not fit to be shown.

In the model of a fuzzy V-chip in figure 2 there are still six fuzzy sets representing the various levels of content, but each fuzzy set spans the universal space. This means that any value of content will have a level of membership in each set. Having a membership in each set allows the aggregation of sets into a final set that spans the universal space. Also, the membership sets fill the universal space, meaning that each element has a membership of one in some membership set. As in the case of classical theory, there are universal spaces for each of the types of content, with the same fuzzy sets representing the levels of content.

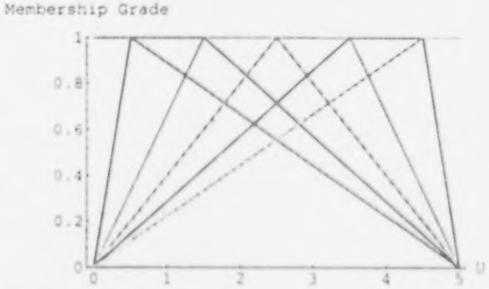

Figure 2: Model of a fuzzy V-chip

In this model, the approach taken in deciding whether or not to pass a show is somewhat different than the approach of the current V-chip. In order to come up with a single representative rating set for each show, and for the content threshold set, the individual sets are aggregated by one of several different methods. The first, and simplest method discussed, is done by taking the min-intersection of all of the individual content rating sets to produce a rating set. The min-intersection of the individual content threshold sets is taken to produce a threshold set. After the rating set and threshold set are produced, they are compared against each other. If the rating set has a higher content level than the threshold set, it is blocked.

The aggregation of sets is done for several reasons. The most important reason to aggregate the sets is to take into account all criteria of the rating of the show to decide whether

BEST COPY AVAILABLE

or not to block it, instead of taking individual ratings into account. This allows a show with an overall low level of offensive content to make up for having a high level of content in a specific area. Aggregating sets also allows for the use of more sets to bias the outcome set. For example, a show with high levels of content that is educational and informative, or is presented in a serious manner can be offset by a bias set to reduce the overall set. A final advantage in aggregation is that only one set of information, a cumulative rating, needs to be sent over the airwaves for comparison to the threshold set, thus saving valuable bandwidth.

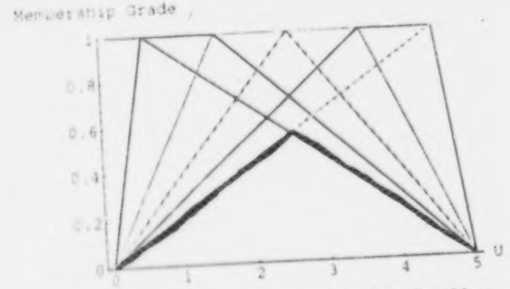

Figure 3: Graphical representation of the "zero and five" problem

Problems dealing with information loss arise when min-intersection is used to aggregate the content sets in figure 2. The most vexing problem involves any show that has both individual rating content sets of five and zero, as shown in figure 3. Due to the shape of these sets, when a show of this type is aggregated, only the five set and zero set are important, and all other information about the show is disregarded. Any show with a five set and a zero set will end up with the same resultant rating set. The other main problem is that of multiple sets. If there are duplicate content sets, only one of them is important in calculating the resultant set, the other is not noticed. Clearly this information loss needs to be avoided by use of a different form of aggregation.

IMPROVEMENTS IN CREATING THE RESULTANT SETS

By use of the product operation to determine the resultant membership sets, many of the min-intersection problems are eliminated. First, the "zero and five" problem no longer exists because the information from all content sets is retained by the resultant set. Also, product takes into account multiple uses of the same content set, and weights the resultant set properly using the information of the duplicate sets. Overall, the product operator is much better at weighting the resultant membership set than the min-intersection operator. Product, however is probably not the most mathematically correct operator to use.

For mathematical correctness, an average would seem to be the best way to find the resultant set. Using an arithmetic mean gives probably the most mathematically correct averaging, and is just as effective as product at removing the min-intersection problems from the weighting. Arithmetic mean also produces sets with higher membership values, and larger fuzzy sets using more elements of the universal space.

The method used to compare which set is larger involves individually finding the center of area of the rating set and the threshold set. The centers of area are discrete numbers between zero and five. If the center of area representing the rating set is greater than the center of area representing the threshold set, the show is blocked. This causes the advantages of using arithmetic mean to be near useless in deciding whether or not a show is blocked. In the final determination, using product or arithmetic mean is up to the discretion of the user, depending on how the rating set and threshold set are compared. Other methods of comparison include finding Hamming Distance, or the MAX and MIN fuzzy operators.

MULTIPERSON DECISION MAKING

To allow for more than one user to decide the threshold set, one of two things must be done. Either all the users' sets must be aggregated to determine an all encompassing threshold set, or a rating set must pass each individual threshold set. To better approximate real reasoning, the latter was chosen.

In a family, a child will ask each parent if they can watch a particular program. The final decision is determined by how much the program is liked or disliked by the individual parents. For example, if Mom dislikes a show greatly, but Dad is somewhat ambiguous about letting the child watch the program, the child will more than likely not be able to watch the show. The final decision is a sort of compromise between the two individual decisions. This is what was implemented by equation (1) using fuzzy arithmetic operators.

$$F(Rule1, Rule2, Show) = (Rule1 - Show) + (Rule2 - Show) \quad (1)$$

The algorithm takes into account a numerical value of the difference between the threshold set and the rating set. Passing is represented by a positive value, failing by a negative value. It sums the results of passing or failing, and if the final number is positive or zero, the show passes; if it is negative, the show is blocked.

CONCLUSIONS

It is obvious that the current model for the V-chip is inflexible and somewhat inaccurate as a model for something as complex as a television show. The ability of fuzzy logic to model linguistic variables offers hope for a rating system that better approximates the real world decision of whether or not a person wants to view a television program. Hopefully the simple solution modeled currently can be implemented into an intelligent system that will save people time searching for appropriate television programming.

Effect of Thin Film Disk Texture on Magnetic Recording Head-Medium Clearance Measurements

Daniel Yau

Department of Electrical Engineering and Computer Science
Tufts University
161 College Ave.
Medford, MA 02155

Faculty Advisor:

Chorng H. Chang

The quest for a larger magnetic recording areal density is the primary factor underlying magnetic storage developments. The reduction of physical spacing between the magnetic transducer and recording media has enabled incredible progress in storage density improvements. However, the current optical methods used for measuring this clearance are time consuming and cumbersome. A novel method is clearly necessary.

In this paper, the effect of thin film disk texturing on head to medium clearance values is investigated. Physical clearance values representative of the analogue readback signal analysis are measured. Readback signal resolution values are also measured. A comparison of ten vendor 95mm Co-alloy thin-film disks is completed and verified. The resulting clearance values strongly correlate to disk surface texture. Flyheight values remain appreciably constant. Uniformity of disk surface texture is more influential than the quality of the analogue readback signal resolution over the accuracy of clearance values. Clearance values can now be taken efficiently. Also, quick and accurate *in situ* clearance measurements are now possible.

I. INTRODUCTION

The quest for a larger magnetic recording areal density is the primary factor underlying magnetic storage developments. The reduction of physical spacing between the magnetic transducer and recording media has enabled incredible progress in storage density improvements. In an actual disk drive, the magnetic transducer or head is mounted on a slider which is designed to fly over the rotating disk. The gap formed between the slider and disk makes up the largest portion of the total head to medium spacing. As this gap is reduced, an accurate and rapid clearance measurement becomes increasingly important.

A clearance measurement strongly correlates to the disk surface texture. Therefore, using this measurement it is possible to make comparisons of different disk types in regard to their surface properties and physical characteristics. Measurement results will aid in the development of both head and disk design so as to bring the industry closer to optimizing the magnetic storage process.

It is evident that head to medium spacing is extremely vital to the storage industry. A reliable and robust method is necessary to determine this value. The measured clearance values in this report are derived from specific characteristics of the analogue readback signal of the recording head. Therefore, the method only needs access to this readback signal. Previously reported systems use an optical approach which was limited by the requirement that the two surfaces be substantially coplanar. A newer laser interferometer system was then introduced which solved this problem to some extent. However, even with this newer design, it was extremely time consuming to characterize a full rotation due to the significant amount of trace averaging necessary to reduce differences arising from random rotational sampling points. This became an even larger problem when simulating modern disk drive motor characteristics which halt rotation in only several seconds. In addition, *in situ* testing of manufactured disk drives was not possible with this optical method. Utilizing analysis of the readback signal to obtain clearance measurements, it is possible to obtain accurate clearance vs. velocity measurements in a minimal amount of time. In addition, rotational synchronous sampling allows for clearance values to be taken from the same point on each rotation, eliminating the need for trace averaging. Also, it is now possible to simultaneously analyze the resolution of the analogue readback signal during the measurement procedure, in addition to obtaining measurements for disks inside an actual completed storage product. It is obvious that this more advanced process is not only more flexible, but will also result in clearance values which are more accurately representative of the true head and disk surface characteristics.

The main purpose of this report is to discuss results from a clearance comparison of ten different disk types using measurement data from the processing of the analogue readback signal. The focus will be on disk surface characteristics. Therefore, the same recording head is used throughout the experiment. Due to confidentiality restraints, each disk will be referred to as disk1, disk2, etc. The clearance measurements will be compared and verified with data from various optical and physical texture analysis tools. From the analysis presented in this report, it will be made evident that accurate head to medium clearance values derived from an analysis of the analogue readback signal is truly representative of various disk surface textures.

II. EXPERIMENTS

Recording experiments were conducted using vender 95mm Co-alloy thin-film disks and magneto-resistive (MR) thin-film heads in a precision teststand. The various disks consisted of cross-hatched, pad, tape, diamond and laser textures. An orthogonal mount (i.e. 0 skew) of the magnetic recording head was used for all clearance tests in this experiment. The head had a gap flyheight specification of 65nm at 8.5m/s as measured by a Phase Metrics flyheight tester. Tracks of equidistant transitions were recorded using a write current of 70mA$_{pp}$. Readback signals were read using a MR read bias of 13mA$_{pp}$. The write frequency was held constant at 2.5MHz. Tracks were written at radii of 45, 40, 35, 30, 25, 20, 19, and 18.5mm. Data zone measurements consist of those measurement results from 45 to 25mm. Landing zone measurements consist of the remaining 3 test radii. This differentiation is used because of landing zone bump texturing used on the inner radii of laser textured disks. (typically <20mm)

A spindown from 8.5m/s was performed at each test radii after a track was written and verified. This ramping was done using a function generator with a 20mHz frequency and a variable duty cycle to adjust for different rotational periods at various radii. Spindown was terminated at a velocity such that a roll-up due to the positive crown slider was observed after the landing point.

Each test disk was divided into 8 sectors. 16 measurements were taken per sector, the first of which was a velocity measurement. The latter 15 consisted of clearance measurements. Full speed readback signal resolution measurements were taken for 2 complete revolutions.

The velocity vs. clearance spindown profiles clearly show the clearance, clearance margin, and touch-down point for each test. The clearance values in this report represent distance from the nominal flying height at 8.5m/s to the rest height at landing. (This is not to be confused with flyheight values which represent distance from the nominal flying height to the mean roughness plane.) Clearance margin values represent distance from the nominal flying height to the point of first contact with the disk surface. (i.e. peak roughness or R_p.) This has strong correlation to take-off height (TOH) values, however, due to the ambiguity of the TOH definition, it may be more proper to use the velocity at this point of first contact for comparisons. Touch-down values represent the point at which the head is at its rest height above the mean roughness plane. This can be associated with the absolute minima of the roll-up at then end of each spin-down curve. (see Fig. 1)

The rotational synchronous sampling used in this measurement procedure also provides the basis for plots consisting of clearance and resolution vs. angle. Clearance variation plots are extremely useful for viewing clamping induced warp, while resolution variation plots are helpful for determining magnetic variation along the write track.

A scattered light roughness verification measurement was handled using a device which aimed a focused laser beam at the disk surface and measured roughness corresponding to the resulting intensity of the scattered light. This device was designed to take measurements in arbitrary units. Therefore, results were only used for comparison purposes.

Tencor roughness measurements were taken using a Tencor P-12 Profiler with a stylus radius of .1μm and no data filtering. This instrument was used mainly to obtain R_p and R_q values. Sweeps were completed using 1mm lengths and both 8 and 16 samples per radius were measured. Both radial and tangential sweeps were performed to characterize differences in results due to the various types of disk texturing.

III. RESULTS AND DISCUSSION

The readback signal full speed resolution reference is based on a resolution value of 115nm. Note that this value is obtained from a calculation involving the half amplitude pulse width (PW_{50}) of the head signal obtained from a measurement using the head/disk combination specifically designed for this head. Because of an offset parameter which can be adjusted, the magnitude of this value is arbitrary. However, the units are in nanometers. The offset was held constant for all measurements taken for this experiment, therefore the magnitudes of the results are relative. A poor readback signal content correlates to a higher resolution value. Because the resolution units in nanometers can cause confusion with both clearance and flyheight values, resolution units will be left out from this point forward.

Full speed resolution measurement results show that 4 disks, disk6, disk7, disk8, and disk10 show poorer resolution than those disks belonging to the rest of the test set. Therefore, it is noted that clearance measurements *may* be affected as a result. Full speed readback signal resolution is better for laser and diamond textured disks, than for tape and pad textured disks. (see Fig. 2)

Take-off (landing) velocities (TOV) determined from the clearance measurements clearly correlate to disk surface roughness. A rougher surface is expected to have a higher TOV than that of a smoother surface. This is precisely what is seen from the test results. Laser textured disks such as disk1, disk2, and disk3 exhibit landing velocities of .8 to 1.0 m/s in the data zone. Landing zone bump heights for these disks are 40.0, 22.5, and 27.0nm respectively. Landing velocities in the landing zone are 3.6, 1.7, and 1.9m/s respectively. TOV measurements for pad textured disks such as disk6, disk7, and disk8 range from 1.2 to 1.7m/s. TOV results for tape textured disks such as disk9 and disk10 range from 1.0 to 1.5m/s. Finally, the TOV results for diamond textured disks such as disk4 and disk 5 range from .8 to 1.0m/s.

BEST COPY AVAILABLE

From the TOV data, it is clear that laser and diamond textured disks are most competitive in terms of their generally smooth texturing. Mechanically textured disk surfaces result in noticeably higher TOVs. The head requires more physical distance to clear the roughness upon a spinup, while it touches-down at a higher velocity during a spindown. This behavior strongly correlates to the clearance measurements taken on these disks as well.

The average clearance measurements for the laser textured disks range from 51.4 to 52.8nm, while the average clearance for pad textured disks range from 35.8 to 46.8nm. The average clearance ranges for tape and diamond textured disks are 43.4 to 51.4nm and 44 to 48.2nm, respectively. Average clearance values for the landing zones of the three laser textured disks are 21, 41, and 35nm respectively. (see Fig. 3)

A lower clearance is easily correlated to a rougher surface, while a higher clearance can be attributed to a smoother surface. This is because a rougher texture has less distance between the surface and the flying height at nominal velocity. This is just the opposite for a smoother textured surface.

Particular attention should be paid to the laser textured and diamond textured results. Both exhibit identical TOV behavior, however, their clearance comparison show appreciable differences. This can best be explained by variation in the roughness uniformity across the disk surface. The laser texturing provides for a more even surface uniformity, while the diamond texturing cannot match this. From this theory, it is expected that the R_p values for the diamond textured disks are higher than for the laser textured disks. This is primarily due to the fact for two different disk surfaces with the same TOV, the mean roughness plane for the less uniform surface should be lower than that of the more uniform surface. This is essentially what is seen from the Tencor R_p measurement results. (see Fig. 4)

Clearance variation from track to track for cross hatched surface textures such as that of disk8 is exhibited in the data results. A "roller coaster" up and down behavior is clearly present in a clearance vs. radius profile. As expected, this is also evident in the scattered light measurement of the same disk type. In fact, a pattern can also been seen whereas the higher clearances essentially correlate with lower scattered light intensity, while the lower clearances essentially correlate with higher scattered light intensity. This is also the behavior with the other test disks. (see Fig. 5)

Clearance variation along a single track at a set radius such as that which is exhibited by some additional samples of disk7 and disk8 is clearly evident in the scattered light measurement analysis as well. The scattered light intensity around the radii in question varies significantly. The rotational synchronous sampling makes it possible to trace the higher roughness rotational range to the same location of higher intensity on the scattered light intensity plots. Accordingly, this clearance variation causes a higher sigma value in the clearance data results. Spindown profiles from the 8 sectors of the disk surface varies by more than 20%.

Because of surface variations from disk to disk, flyheight specifications for each head are used, rather than clearance values. Therefore, to verify the clearance values from this experiment, individual flyheight values are calculated based on the experimental clearance data.

To most accurately determine the correct flyheight, a TOH for each individual test disk should be added to the clearance for the respective disk. Because this TOH data is not readily available, the peak height of the disk surface roughness (R_p) as determined by the Tencor P-12 is used instead. TOH is heavily related to the R_p value. There remains a difference between the two primarily due to the small additional air bearing that is, and should be, included in the TOH measurement. However, this is not included in the R_p measurement. The air bearing is representative of the air channeled into the surface grooves trying to escape, therefore pushing upwards resulting in a slightly larger flyheight.

R_p measurements obtained from the radial and tangential sweeps do not show appreciable differences. Comparison tests of both 8 and 16 1mm sweeps also show no noticeable differences from the measurement data. With the exception of the results from disk8, flyheight values range from 59.2 to 68.8nm. This is with the absence of the small upward-pushing air bearing previously discussed. However, it is clear that results are still extremely close to the specification of 65nm at 8.5m/s.

A low flyheight of 54.3nm is obtained from disk8. Results from this disk show one of the highest R_p values (second only to those of disk6), the lowest clearance values, and fairly poor resolution values. RMS roughness (R_q) obtained from the Tencor measurements are also high, again, right behind those of disk6. It is noticed that a large amount of variation is present in the clearance data at each test radii due to the mix of a courser surface combined with the cross hatching texture This causes sigma values which are much larger than those of the other test disks. It is assumed that the poor readback signal resolution complemented by this high clearance variation is the cause for the low experimental flyheight.

Tencor R_q values correlate directly with the clearance values obtained from each spindown. Laser textured disks show the lowest R_q values followed by diamond, tape and pad textured disks in increasing order.

IV. CONCLUSIONS

Clearance measurements from an analysis of the analogue readback signal strongly correlate to disk surface texture. Spindown profiles clearly show the transition points of the head to disk interface. The

BEST COPY AVAILABLE

clearance at touchdown represents the first point of head to disk surface contact. The touchdown velocity associated with this point can be matched with a TOH value which, when added to the total clearance value, will yield the true flyheight from the mean roughness plane of the disk to the nominal surface of the head. Because R_p values are strongly related to TOH values, it is feasible to use R_p values in lieu of TOH. However, one must understand that a slight error is presented since the small upward-pushing air bearing due to trapped air in the roughness valleys is not taken into consideration for the R_p measurements.

Rougher surface textures yield a lower clearance value, while smoother surface textures yield a higher clearance value. However, flyheight values remain fairly constant and compare very closely to the true flyheight specifications of the head.

The analogue readback signal resolution is representative of the quality of the write signal. However, uniformity of disk surface texture influences the accuracy of the clearance values more heavily.

Rotational synchronous sampling provides for more accurate clearance and resolution measurements. Clearance variation vs. angle plots clearly show variations in disk surface roughness around a single track. Large sigma values in a spindown curve provide for easy noticing of this characteristic.

Clearance measurements can be easily and efficiently taken from an analysis of the analogue readback signal. Results show that smoother disk surfaces have a lower texture depth than rougher surfaces. This provides for reduced head to disk interaction which may cause poor readback signal resolution, as well as eventual disk drive failure.

The lack of use of Life-Cycle Engineering (LCE) technique in the design of production facilities has led to the design and development of the "Self-Evaluation Tool" (SET). The SET is a component of a software system called "Life-Cycle Advisor" that will help project managers to become aware of, and comprehend, all the factors that affect the Life-Cycle Cost of a production facility. For example, the SET will help project managers treat the Life-stages of a building as parts of a complete evaluation.

The SET program was developed with the Visual Basic v3.0 programming language due to the friendly environment characteristics. The SET program consists of windows that display multiple choice questions that cover a variety of project areas. It attempts to establish the scope of the LCE program for a particular structural firm. Buttons with captions of 'Backward', 'Forward', 'Quit' and 'End' appear in each window. The 'Forward' button allows the user to move forward through the program and the backward button does the opposite. The 'Quit' and 'End' buttons will enable the user to conclude the questionnaire whenever he/she wants. As a result of the 'End' command button in window with question twenty-three, the proceeding window will be used to display the users' responses. Menus appear in the last two windows. The menus enable the user to save, print, copy and edit the existing file. Message boxes such as 'Save As' and 'Print' boxes give a more professional look to the SET software system. Overall the SET program will help owners save money by pointing out that designers should consider many factors in both cost and performance throughout the planning horizon of a facility.

BACKGROUND

The Construction Industry Institute (CII) research team #122 believes that there are several reasons for the lack of Life-Cycle Engineering (LCE) of production facilities. One of these reasons points to managers who make their decisions in an unstructured and data-limited environment during the initial planning phase. Another reason for the misuse of LCE analysis is based on the idea that project managers do not understand the relationship between LCE factors. Managers do not consider factors such as the investment of design, construction, maintenance, renewal and decommission of production facilities as part of a combined process of evaluation. Finally, there is a belief that miscommunication between members also becomes part of the problem. A vast majority of the decisions made by individuals at multiple companies do not share common sets of information or methodologies with respect to project life-cycle goals. With these problems in mind, the CII initiated a project that will help project managers and designers do two things. First, the CII intends to help project managers and designers understand the relations between all the factors that affect the LCC of production facilities. Second, the CII intends to improve the decision of those who have the power to affect the LCC of production facilities. The "Self-Evaluation Tool" is one of the elements of the "Life-Cycle Advisor" project that was developed as a software system to help designers and project managers use LCE techniques more efficiently.

PROCEDURES FOR DEVELOPMENT AND IMPLEMENTATION

The overall project was divided and distributed to different members of the research team. The main goal of this project consisted of the creation and automation of the "Self-Evaluation Tool." The SET has been developed and implemented with the utilization of the Visual Basic v3.0 (VB) programming language. One of the goals of the SET program was to provide a Graphical User Interface (GUI) to the user. The SET provides four characteristics similar to any 'MS-Windows' program. First, the SET provides command buttons in every window that control the display of twenty-three multiple choice questions. The twenty-three windows containing the multiple choice questions are able to store the selected choices. Later, the chosen answers will be summarized in order as Figure 7 in the Appendix shows. Second, it contains instructions on how the user can mail or email the selected file. Third, visible menus give the user the ability to edit the file as he/she wishes by saving, cutting, pasting, exiting or returning to the beginning of the program. Fourth, message boxes for a more professional look appear during different situation. These message boxes have two purposes. First, they provide messages restricting the user from proceeding upon an invalid operation. Second, it provides the user customary boxes such as 'Print' and 'Save As' that are familiar to any person who has used a computer before. These boxes give the user several options just like the options that 'Microsoft-Windows' gives.

To accomplish these tasks Visual Basic v3.0 was learned. VB is an object oriented computer programming language. The programmer became familiarized with programming environment by reading a book called VB in 12 Lessons. The book VB in 12 Lessons takes the programmer through "mini-programs" that simulate the way bigger programs should behave. The skills learned were improved by reading a book called Visual Basic3 for Windows. Finally all the knowledge was applied into Visual Basic v3.0 for the implementation of the "Self-Evaluation Tool." Two methods for the creation of the GUI were approached.

Method#1

The first method (method#1) that was approached displayed the 23 questions using a master window. The captions of 'Labels' that displayed the question headings were controlled with 'Forward' and 'Backward' command buttons. These buttons were coded with 'If Then' statements. Method#1 reduced the execution time of the program since there was no need for opening new windows every time a new question was to be displayed. The execution of this method did not easily allow the storage of selected choices for individual questions. For example, when a particular choice was selected for a particular question, the same choice for the next question automatically became selected. For this reason, a second method was attempted using individual windows for each question.

Method#2

Method#2 was successful because there was no difficulty storing the selected answers as the user made a choice. For example, if the user selected choice#1 for a window titled Question#1, choice#1 of window titled Question#2 did not become selected if the user did not check the choice. This was accomplished because the codes for each window are unique and separate to that particular window. This method slowed the program because there was a need for opening and closing new windows every time the next question was requested. The 'Loading' commands for all the files in the beginning of the program compensated for the slowness of the execution. The window titled 'Answers' contains the users' answers to all the questions. The purpose of this window is so that the user can mail it to the CII by selecting the options on the menu. Upon receiving the mailed answers, the CII will be able to improve the quality and quantity of life-cycle engineering techniques by commenting on the user's answers. The CII will grade this questionnaire and provide advisement to the user of the SET program.

The menus play a big role in the implementation of the SET. The menu in the 'Answers' window contains 'Print', 'Exit', 'Back to Questions' and 'Edit' options. The 'Edit' option automatically opens up a new window with new menu. This new window contains 'Save As', 'Display Answers', and 'Help' options. The 'Save As' option will save the edited file same as a normal 'Save As' command does in other programs such as 'Microsoft Word'. The 'Save As' command provides message boxes in case the user mistakenly tries to overwrite an existing file or cancel the 'Save As' command. Method#2 was very useful to advance the development of the SET program.

The goal of developing a program that attempts to make the user more aware of Life-Cycle Engineering Techniques was successfully accomplished. The characteristics of the SET program are as follows; It automates the questionnaire, stores the choices in the check boxes for individual questions, prints, calls the stored answers and displays them in a window titled 'Answers'. All of these characteristics are accomplish with a simple clicking of the mouse. Finally the SET program gives the user the ability to copy the selected options so that she/he can paste them on an email window.

RESULTS OF GRAPHICAL USER INTERFACE

The GUI contains titled windows that will let the user know where and how far he/she is in the program. Figure 2 shows instructions of what to do to run control the program. The windows provide a question along with a set of 'Check boxes' and captions for each factor to be considered by the user. Three buttons were placed at the middle of the screen. These buttons are labeled 'Backward', 'Forward' and 'Quit'.(See Figures 3-5 in Appendix for view of the windows and command buttons.)These are accessed with a simple click of the mouse. They can also be accessed by tabbing until the focus is set to the desired button and pressing the space bar. All the windows that display questions contain the same format. For the benefit of the user, after choosing 'Quit', a 'Frame box' appears requesting the user for a yes or no answer. This is a check to make sure that the user wants to quit. At the end of the questionnaire the 'Quit' button changes to the word 'End'. When the user clicks the 'End' button and accept to finish the questionnaire, an instruction window appears so that the user knows what to do next.(See Figure 6 in Appendix.)The program brings the last window up with a command button 'Enter' in the middle of the screen. Finally, the answers will appear when the programmer clicks the 'Enter' command.(See Figure 7 in Appendix.)These tools will serve two purposes. First, the SET will make it possible for the CII to advise the user upon receiving the mailed answers. Second, the SET will help the user become aware of all the different factors that could possibly affect the Life-Cycle Cost of production facilities.

ANALYSIS

Even though the SET program was developed and implemented, the consideration of a master window for all questions will minimize the amount of memory needed to run the program. It is possible for all the questions to be combined in one window using 'If Then' statements in the code. More time must put into the logic of the coding if less memory is critical for the execution.

For this project, there were two questions asked. First "Will the program be able to compile successfully?" The program had to be done in a certain amount of time. Therefore, method#2 was chosen. The second question was "Is the GUI of the SET user friendly?" This requirement was satisfied when the SET was experimented on several people such as Martin, Adriana, Lüi, Hugo, Amy and many others. These people had no knowledge of the project but had previous experience with other programs written in C++ and FORTRAN. Their feed back pointed out that the running the SET was very simple. Although saving memory was not a priority, it should be taken into consideration for future versions of the program. Other factors were kept in mind, but the finish product and user friendliness of the product were of higher priority. Therefor the use of Visual Basic v3.0 programming language was most appropriate for the implementation of the SET.

CONCLUSIONS

The SET program compiles successfully. With the use of the SET, the designers will be able to mail their data to the CII. The CII research team #122 will be able to advise project managers and designers how they can improve the use of LCE techniques. The SET program will attempt to help owners save money once the designer considers factors in both cost and performance throughout the planning of a new facility.

FUTURE RESEARCH AND RECOMMENDATIONS

It is suggested that future work be done on the SET project. A window at the beginning of the questionnaire allowing the user to open and modify the already existing data files should be implemented. This window could appear after the first window that the user sees when the SET is run. Figure 1 is the title window. This can be done with the usage of menus similar to those in the 'Answers' window shown in Figure 7 of Appendix. The file menu should contain 'New' and 'Open' options. The 'New' menu command will let the user start a new file.

The 'Open' option will allow the user to call a file that was saved in a separate folder. The execution of the SET should have ways to link to the selected file. This linkage should enable the menu commands in the 'Edit Mode' window. If this linkage is accomplished, the 'Edit Mode' window will allow the user to move back and forth throughout the program without the need of further coding. Finally, the program could be upgraded to Visual Basic v4.0 the Windows95 edition.

ACKNOWLEDGMENTS

The author wishes to express it most sincere appreciation to Dr. John Wilson, and Matt Rowe for their inspiration and advisement. Dr. Bavarian, Dr. Dijulio, Dr. Shively for the opportunity of be part of the GD research team. The National Science Foundation for monetary support. Nevertheless, my family for all the encouragement and understanding.

Excessive Noise Levels Enhance
Special Effects, Are You Aware?

K. Osborne

Department of Management and Accountancy
The University of North Carolina at Asheville (UNCA)
Asheville, NC 28804-3299

Faculty Advisors

D. Lisnerski and R. Yearout

Entertainment special effects has been greatly enhanced by audio technology. Increasing sound levels and frequencies without a loss of clarity is now an effective tool for evoking audience response. Although the public may be aware of the hazards associated with power equipment and firearms, it rarely considers music or multi-media events as potentially hazardous. A recently released action film containing special effects with excessive noise levels was selected for investigation. Sixty-four percent of the variation approval rating could be explained by noise level. Although 70% of the subjects could recall specific scenes containing excessive levels, only 34% could recall quiet scenes. Appeal may be associated with the basic "flight or fight" instinct, thus audiences may accept excessive noise levels in an entertainment environment that otherwise might be unacceptable.

INTRODUCTION

Since the public is frequently unaware of hearing damage until it is acute, hazardous noise levels associated with leisure activities is of growing concern. Although the public may be aware of the risks associated with power equipment, concerts and firearms, it does not consider activities associated with amusement parks, such as simulation, or theater multi-media presentation as potentially hazardous. Previous investigations by Brown and Yearout [1991] and Gray, Swaby and Schulze [1995] showed that, with the exception of rock concerts, participants give very little thought to excessive leisure noise level exposure. These observations included professionals who were fully aware of the risks associated extended exposure but elected not to alter their behavior.

Meloni and Kruger [1996] found that the annoyance of impulsive noise stemming from machine gun fire, was less than the annoyance of automatic cannon shots at a military training range. Subjects were exposed to both machine gun and cannon fire simulations in a home setting. Higher disapproval of the cannon volleys can be attributed to the type of environment relative to the expected noise tolerance. In the home, subjects do not accept the unexpected annoying sound of either weapon. This study illustrates a lower approval rating and less tolerance for the annoying noise if it is foreign to the environment. Bubb [1996] demonstrated recall and response effects in relationship to expected noise levels. Subjects responded to noise levels associated with a given task. Perceived acceleration of an automobile's motor and noise level of the motor were directly related. Brown and Yearout [1991] illustrated that loudness equates to perceived power. This phenomena appears to be just as prevalent in film and amusement park activities such as racing simulation.

Misconceptions or lack of awareness concerning hearing loss risk creates an ethical issue for producers and promoters who are aware of the hazard. Producers and promoters should ensure that noise level data for popular amusement activities are obtained. This management responsibility also should include disclosure of not only the noise levels of an activity, but it's associated risk as well.

EXPERIMENTAL PROTOCOL

Introduction. This paper focuses on whether or not a subject's recall and response to a multi-media event, specifically film, has a relationship with excessive and or unacceptable noise levels. Also examined was the ability of the subject to discern a specific event's noise level. Several recently released films were monitored. Of the potential candidates, films that contained special effects and excessive noise levels (dBA) greater than

SLOW MAX(105), PEAK(115) and 3 dB SEL(115), a recently released science fiction action film was selected. This film when viewed at a local sound enhanced theater registered the following noise levels: SLOW MAX (109 dBA), PEAK (120 dBA) and 3dB SEL (119 dBA). The film then was observed to locate several scenes that contained significant noise and scenes that contained noise levels that were within the acceptable range. Data collected by using a specially designed multi-item semantic differential scales.

Subjects. Sixty-five volunteer subjects (27 male, 38 female) were recruited from the University community. These were randomly assigned (based upon individual schedules) into four groups. Subjects' median age was between 20 to 25 years.

Laboratory. UNCA's multi-media classroom was chosen for the experiment. Although the noise levels could not exactly duplicate those of a typical theater, this high technology classroom had the capability to control noise levels within +/- 2 dBA. Speakers and screens were positioned to simulate an environment that was quite comparable to a contemporary multi-theater complex auditorium.

Experimental Design. The four selected groups were then randomly assigned to one of the following two conditions, loud (PEAK dBA > 100 dBA) and not loud (PEAK dBA < 90 dBA). Average exposure time was 2.3 hours. Immediately after the conclusion of the film, subjects were administered the semantic differential scale survey.

RESULTS

Analytical techniques. To insure that the data was homogeneous, Levine's Test for Homogeneity of Variances was performed at the 0.05 significance level. When conditions for normality were met, Analysis of Variances (Type III Sums of Squares) and Least Significance Differences (LSD) Tests were applied. Where data was determined to be non-parametric, Satterthwaite's Approximation with Bonferroni's Adjustment were used in lieu of the Analysis of Variances [Johnson and Milliken, 1984]. Frequency tables were applied to determine significant variables for potential correlations. Once a variable was determined to be significant, further analysis which included correlation, General Linear Model (GLM) and regression analysis procedures were applied where appropriate.

Results. Preliminary analysis determined that there were no significant interrelationships between the two "loud" groups and the two "not loud" groups. Thus the investigator was permitted to pool the four groups into two groups, "loud" and "not loud". Significant statistics for pooled data groups are in Table 1.

Table 1. Pooled Data for Significant Variables/Conditions

Loud Group (sample size = 30)			Not Loud Group (sample size = 35)		
Variable	Mean or Rating	sd	Variable	Mean or Rating	sd
PEAK	114 dBA	12	PEAK	87 dBA	3
SMAX	104 dBA	10	SMAX	80 dBA	3
3 db SEL	123 dBA	4	3 db SEL	110 dBA	4

Other Variables/Perceptions	Other Variables/Perceptions
Film Approval Rating: 88% on a 100% scale	Film Approval Rating: 69% on a 100% scale
Median Perceived Noise Level: 105-110 dBA	Median Perceived Noise Level: 85-90 dBA

ANALYSIS

General. There were no significant age or gender effects. The two group means for all selected variables were statically significantly different at the 0.05 significance level. Variables of interest to the research question are addressed the following sub-paragraphs.

Recall. Subjects were queried to identify the loudest scene, next loudest scene and third loudest scene in the film. Seventy-seven percent of the subjects identified the previously selected scenes in order of loudness (Figure 1). When subjects were asked to identify quiet scenes, 34% could not recall any scene as being quiet. Of those that could recall a quiet event, no more than 6% identified the same scene. One specific scene that combined excessive noise with surprise was recalled by over 90% of the subjects. Though this scene was not the film's loudest, it does typify the effective use of technology to evoke response through visual and audio stimulation.

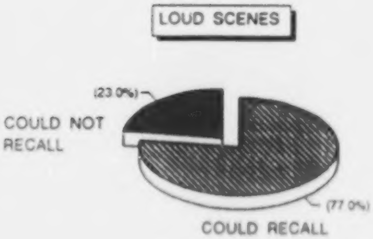

Figure 1 Film Recall Relationship with Noise Level

Slow Maximum (LSMAX) Levels. Permissable noise exposures by OSHA maintain that a sound level slow response of 105 dBA should not exceed one hour in the workplace on any given day If sound levels exceed the established exposure limits, OSHA requires the employer to either reduce noise levels or provide personal protection equipment to employees [Gray, Swaby, & Schulze, 1996] Although Federal guidelines do not apply to noise exposure from leisure activities, one needs to realize that the loud group, whose noise level exposure slow max reached 104 dBA for 2.3 hours, is more than double allowable limits

Discomfort Perceived noise levels for the complete film were estimated by comfort/discomfort votes on a semantic differential scale much like the Borg Vote Scale may be used to estimate heart rate Votes for all responses are illustrated by percentage in Table 2 and Figure 2

Table 2 Estimate Film Noise Levels Based on Discomfort

vote (%)	(1)	(2)	(4)	(7)	(29)	(5)	(36)	(9)	(7)
	not loud		somewhat loud		loud		very loud		too loud
noise (dBA)	75		85		95		105		>115
discomfort	none		not noticeable		some discomfort		ears ringing		hurt my ears

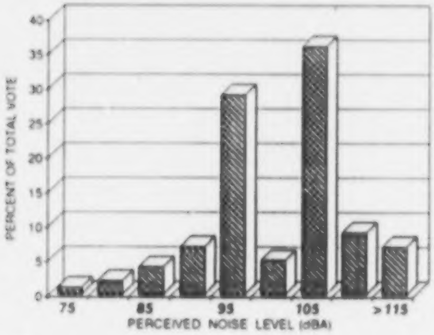

Figure 2 Discomfort Level Percentages

BEST COPY AVAILABLE

Approval Ratings. There was a significant correlation (0.801) between film approval ratings and perceived noise level. A regression model, 0.01 significance level and multiple correlation coefficient of 0.64, will predict that 64% of the variation in the approval rating could be explained by perceived noise levels. Figure 3 illustrates this relationship between acceptance ratings and perceived noise levels.

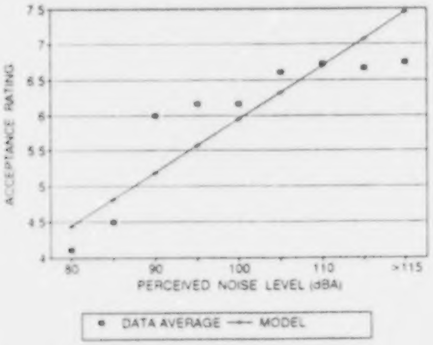

Figure 3. Film Approval Relationship with Noise Level

CONCLUSIONS AND RECOMMENDATIONS

Conclusion. Based upon this exploratory research, it appears that film producers may be taking advantage of current technology to enhance special effects through noise levels that would be unacceptable in the workplace. The louder the special effects, the higher the film rating may be a motivator for film producers to increase noise level. An example is the just released "Star Wars" trilogy that touts an enhanced sound experience. Although audiences are aware of the discomfort from excessive noise, this type of entertainment receives high acceptance. This appeal may be due to the basic "flight or fight" instinct, thus audiences accept these noise levels that under other circumstances might be unacceptable.

Recommendations. Currently, noise level warnings provided by film producers do not exist, and do not adequately explain the potential hazard of current sound technology through enhanced louder noise levels without significant distortion. Film producers should accept more responsibility in educating the public that excessive noise levels in films is hazardous. At the very minimum, films that exceed OSHA standards should include warning of the potential damage to hearing when exposed to loud volumes for extended periods of time. Furthermore, OSHA guidelines for noise exposures should be stated prior to the start of the film, and a statement of the noise level audiences can expect to experience in the film as well. An ideal goal for film producers to meet, ethically, involves a warning at the end of televised commercials for the film, and an opportunity prior to film viewing for patrons to either receive their money back if they choose not to risk hearing loss, or have access to personal protection equipment that the endorsing theater should provide at no additional cost.

Dr Prasad Gavankar

ABSTRACT

Regression analysis is a highly useful tool in experimental designs which target a desired response from machining This design involves (1) the identification of key factors of a milling process, (2) the selection of a quantitative model relating these factors, and (3) an assessment of the model's accuracy in predicting the response This article presents a technique for estimating the surface of machined parts using computer programs for multiple linear regression analysis The goal is to develop response surfaces using mathematical models that (1) accurately predict the response of varying machining parameters and (2) are based on the most significant machining parameters By adjusting the key parameters to specific settings, a targeted response can be realized assuring the functionality of the machined part

INTRODUCTION

Improving safety, reliability, and service life have been the motivation behind research of surface conditions produced by various manufacturing methods Since these surface conditions ultimately affect component performance once in service, component cost and producibility are also affected The emphasis on quality assurance and product reliability increases the importance of recognizing the impact that manufacturing processes have on material properties (Machine Data Center's Handbook, 1983)

Component reliability, therefore, represents the driving force behind this research The ability to predict the surface effects ultimately enables designers to predict component performance As can be seen from the Figure 1 below, the surface effects play a pivotal role in overall component reliability

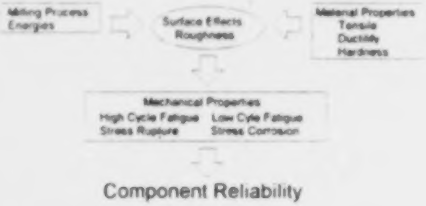

Figure 1 Interaction of processes with materials Machining Data Center's Handbook (1983)

This paper presents a mathematical model for the surface finish generated on steel specimens Data was collected using the Mitutoyo Surftest 402 series 178, utilizing stylus model 178-319 The model's ability to account for changes in the operating conditions while maintaining its success as a prognostic tool is the ultimate goal in the attempt made to model the machining method This test was used to measure and compute roughness average (Ra) values which represent the response variable used in developing the mathematical model

Current work in response surface modeling One of the most significant contributions to statistical methodology in recent years has been the development of systematic procedures for determining, experimentally, those levels of the factors under investigation which produce an optimum response (Ziesel, 1985) Response surface modeling has been successfully applied to many areas of research Surface modeling has been effectively applied to the development of a mathematical model for cutting forces in end milling Inconel 718 (Aluaddin, El Baradie, and Hashmi, 1996) Their model, which was developed in terms of cutting speed and axial depth of cut, was subjected to ANOVA test and was found to be adequate. Khun and Andre (1996) describe a procedure for establishing operating conditions that result in a predicted response close to some target value. The authors included are actively paving the way in response surface modeling and discovering their usefulness as prognostic tools.

Previous work in regression modeling. The diversity and effectiveness of regression modeling has made it widely applicable to many environments. Fields such as crop forecasting, analysis of supply and demand, the study of consumption, market analysis, all have been noble areas for the application of the techniques of regression (Griffin, 1962). Regression analysis is a powerful tool when used for the purpose of predicting (Ziesel, 1995). Regression analysis has been applied in the analysis of the temperature distribution of two dimensional surface buoyant jets (Subramanyan *et al.*, 1995). In addition, these researchers stress the importance of supplementing mathematical models by laboratory and field experiments in order to improve the model's predictive capabilities. In this manner, causal inferences can be made about the effect of certain variables since data comes from experiments (Ziesel, 1995).

Summary of literature in response surface and regression modeling. It is evident that regression modeling is complimentary to response surface modeling since the former stands as a powerful tool in the effectiveness of the latter. Unfortunately, the application of a flexible model able to explain diverse milling situations is as of yet nonexistent. This is largely due to the extreme unique nature of individual machining methods. Experimentally obtained constants can vary widely from one milling situation to another, which in turn, significantly restricts their usefulness as predictive tools for process design (Kulkarni, Chandra, and Jaddale, 1996). However, it is quite evident that if a flexible model is to someday be achieved, it will culminate only as a result of observing and understanding individual phenomenon compiled from the uniqueness amassed from a variety of machining situations. In this light, continued research in the area is well justified and encouraged.

RESEARCH GOAL

The goal is to develop response surfaces using mathematical models that (1) accurately predict the response of varying machining parameters and (2) are based on the most significant machining parameters. By adjusting the key parameters to specific settings, a targeted response can be realized assuring the functionality of the machined part.

The steel specimens were machined according to the parameters illustrated in Figure 2.

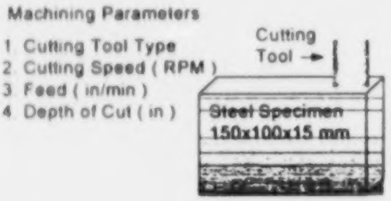

Figure 2. Machining Parameters

Figure 3 below illustrates the manner in which the data was collected and categorized.

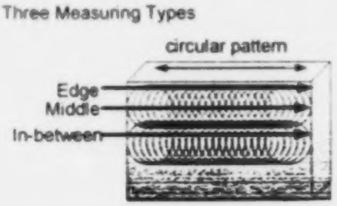

Figure 3. Measuring Types

The circular pattern generated was then tested for uniformity of the response variable, the roughness average.

In order to model the Ra as a function of the key factors affecting the surface, collected Ra values were initially plotted from a single face and visual analysis of the data hinted at a trend as illustrated below in Figure 4

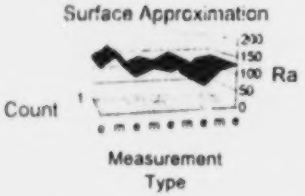

Figure 4 Surface Approximation

From a practical perspective, E measurements were expected to be smoother since the edge of the circular pattern is where an overlap existed between subsequent runs of the cutting tool After conducting an ANOVA of the E and M measuring types, an experimental F value of 9.1 was realized over an expected F value of 9.02., providing evidence that the means of the two measuring types are significantly different Furthermore, a Duncan Multiple Range test at an alpha level of .05 categorized the measurements as being significantly different

Since the trend in Ra values was due to the effect of the cutting tool, face comparisons were achieved by the introduction of blocking By adhering to consistency in the arbitrary selection and use of a single measurement type, Ra variability was effectively diminished

THREE FACTOR FIXED EFFECTS MODEL

This design was developed to study the effects of the three varying factors as shown below in Figure 5 It is well known however, that the cutting forces which are directly related with surface roughness, can generally be considered independent of cutting speeds within practical speed ranges (Reid, 1991)

Test#2 Three Factor Fixed Effects Model

3 Control Variables

Cutting Tool Type (A)	Depth of Cut (B)	Tool Speed (C)
- 1/2" Endmill	- .001"	- High
- 1" Endmill	- .005"	- Low
- 2.94 Side Cutter		

Response Variable Ra

Figure 5 Fixed Effects Model

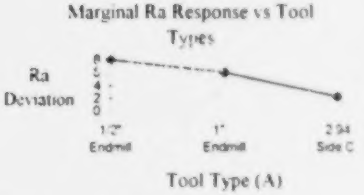
While different cutting tools require different low and high settings, the low and high cutting speed levels were held constant for individual cutting tools In an effort to simplify the calculations necessary, the data presented in Table 1 was coded by dividing through by the smallest Ra value

Table 1 ANOVA of 3 Factor Fixed Effects Model

Analysis of Variance for the 3-Factor Fixed Effects Model

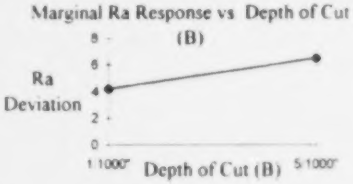
Sources of Variation	Sum of Squares	DF	Mean Square	Fo
Tool Type (A)	136.173	2	68.087	**324222.4**
D. of Cut (B)	31.97	1	31.97	**15223.81**
Tool-Spd. (C)	0.4	1	0.4	190.476
Error	0.0246	12	0.0021	
Total	172.446	23		

~~To assist in the practical~~ interpretation of this experiment, the next figures present plots of the three main effects



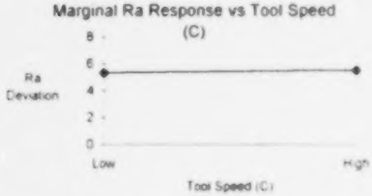
Graph 1 Marginal Ra Response vs Tool Types

From Graph 1, the marginal Ra response due to the tool type used was very significant as supported by the analysis of variance Different tool types yield distinctively different Ra values



Graph 2 Marginal Ra Response vs Depth of Cut

From Graph 2, the marginal Ra deviation increased slighlty as factor B increased This is readily expected since more frictional forces are involved with an increased depth, thus, yielding increased Ra values



Graph 3 Marginal Ra Response vs Tool Speed

The marginal Ra response is relatively unaffected by local changes in tool speed as illustrated in Graph 3 above

Since factor A was overwhelmingly significant, the cutting tool stands as the most important factor yielding the corresponding Ra values Therefore, separate response curves are needed for each tool type In addition, 20 or more observations are recommended so that residual analysis may be done more effectively

REGRESSION ANALYSIS AND EQUATIONS INVOLVED

Due to the fact that this research is on-going and dependent on future experimentation, a run through is provided for the analysis of the data to be attained In addition, most research is of the continuing variety and therefore, sequential (Ostle, 1964)

A multiple regression model was fitted to the ½" Endmill data The final regression model was

$$\hat{y} = 198.775 + 105(x_1 - 200) + 16187.5(x_2 - 003) + e \tag{1}$$

CONCLUSION

In this research, a technique has been illustrated for the development of response curves for a milling operation The cutting tool was determined to be the most significant factor affecting the surface roughness resulting from a milling operation Speed and feed were shown to be secondary factors that affect the surface roughness This was verified and confirmed by conducting an analysis of variance of the roughness data The preliminary research also shows that their exist a linear relationship between the speed and feed in a milling operation By conducting more experiments at different settings of speed and depth of cut, a response surface may be achieved by the illustrated method In addition, the response curve will be fitted using the method of Least Squares, confidence and prediction interval planes constructed, and the model will be tested for lack of fit using the F-ratio

While it is understood that cutting tools represent the single most important factor affecting surface roughness, it should be noted that metals of the same type will not always behave in the same manner when subjected to machining While metals may quite often be of the same type, the microstructures may vary immensely among similar metals, this in turn has enormous effects on the physical properties of the material (Reid, 1991) These consideration have not been addressed which in all likelihood play an important role in component performance

The Use of the GRAFCET Approach to Automation of PLC Programming & Control

Janice R. Sansberry

Department of Industrial and Engineering Technology
Grambling State University
Post Office Box 34
Grambling, LA 71245

Faculty Advisor:

Dr. Shueh-Ji Lee

GRAFCET is a high-level graphics-based programming language which uses the Sequential Function Charts (SFC) concept and the top-down design approach to develop the control algorithm for high-end PLCs. In this project an integrated control program development software package named CADEPA (developed by Famic) was utilized. CADEPA can be used to write control programs for PLCs in the GRAFCET language, translate the control programs into executable code for various PLCs, and generate fully documented reports including ladder logic diagrams. In a preliminary study, computer simulation was performed to test the feasibility of the GRAFCET approach to PLC programming. In this phase two study, a local waste water treatment plant is simulated to investigate the suitability of this approach to more complex applications. Experimental study is performed by using an IBM-compatible 486-DX PC and Modicon 984 Compact Programmable Controller.

INTRODUCTION

Programmable Logic Controllers (PLC) are widely used for industrial processes. In general, the hardware includes: a central processing unit (CPU), digital and analog I/O modules, and program recorder/memory for data and program storage. PLCs can carry out different types of control functions at various levels of complexity. Size and memory requirements are contingent upon the scale of the operation. Several PLCs, controlled by a centralized computer, may be used for large processes. Because it is more durable than the PC, the PLC fits well in industrial environments where noise, dust, vibration, and heat are prevalent.

Traditionally, PLC programming has been done using ladder logic. However, with more elaborate processes, ladder logic becomes lengthy and cumbersome. GRAFCET is a high-level graphics-based language that can be utilized to write control programs. GRAFCET uses the Sequential Function Charts (SFC) concept and the top-down design approach to develop the control algorithm, which is "controller independent", for high-end PLCs (How to Use GRAFCET Part I, p. 47). To write control programs for PLCs in the GRAFCET language, an integrated control program development environment named CADEPA (developed by Famic) is used. In addition, it can translate the control programs into executable code for various PLCs and generate fully documented reports including ladder logic diagrams.

The purpose of this study is to use the CADEPA control program development package to evaluate the feasibility and compatibility of the GRAFCET approach to PLC programming. By using this approach, we hope to shorten the control programming process.

METHODOLOGY

The basic GRAFCET GRAPH consists of two graphic elements: "steps" and "transitions". Steps are units which represent physical operations. When a step is activated, the controller performs the action associated with that step. Transitions are conditions which are evaluated to make decisions on whether to activate or deactivate the next step. A transition always link two steps (How to Use GRAFCET Part 1, p.12). As shown in Figure 1, an "application" combines all GRAPHs that make up the complete control process. Similar to subroutines, GRAPHs can also be shared with other applications.

Rules, referred to as the GRAFCET evolution, define how the GRAPH elements follow their sequence (CADEPA, Vol. I, 1986, A-17). They can be summarized as:

Initial steps are unconditionally activated when the program is started or reinitialized;

1) A transition is armed when the preceding step is activated. When the associated condition becomes true, the transition is fired;
2) When a transition is fired, the previous step is deactivated and the step following is activated;
3) More than one transition can be fired simultaneously when the "AND" element is used in a GRAPH.

Once all GRAPHs are created and analyzed separately for syntax errors, the GRAPHs needed are selected to create the application. Now, the GRAPHs must be translated into ladder logic before they can be used on a PLC. PLC hardware configuration, I/O assignments and memory mapping are essential steps in translation. The PLC configurator is utilized to specify the number and type of I/Os, registers and communication ports. Mnemonics are assigned to steps, transitions, I/O and internal variables used in a GRAPH. A specific memory address in the PLC is allocated for each of these mnemonics. Memory mapping defines and partitions the memory for variables used in the program. The CADEPA on-line mode is used to generate the ladder logic and download it to the target PLC where switches and indicators are used to simulate inputs and outputs of the control process. The control process can now be monitored via PLC and personal computer.

In a preliminary study, a simple control system for water neutralization (Figure 2) was successfully programmed in GRAFCET and simulated using an IBM compatible 486-DX2 and Modicon 984 PLC. Our target PLC had 4 kilobytes of memory and used MODBUS communication. In the control system simulated, a sensor is activated in the first basin and pH is tested. A certain amount of acid or base is added depending on the pH value. The mixture is agitated then emptied into a second basin if the pH is between 6 and 8. The water is left for settling before being pumped out. In the GRAPH, the pH sensor is represented by a step. Conditions used in the pH test are represented by a transition. Ten steps and ten transitions were used in the GRAPH to program the water neutralization control system.

In the second phase, a local waste water treatment facility as shown in Figure 3, was the object of our simulation study to investigate the suitability of this approach to more complex processes. This CADEPA "application" contains three GRAPHs: a main program, a pH control sub-program and a clarification sub-program. The main program, which is shown in Figure 4, contains six steps and five transitions. A total of 24 steps (actions), 23 transitions (conditions), and nine variables were used to simulate the actual process. Memory was partitioned for timers, I/O variables, logical and numerical variables, steps, and transitions. During actual simulation of the programs, we traced the operation via computer to locate errors in the CADEPA application and correct them.

CONCLUSION

From our initial study, we concluded GRAFCET programs were easy to write and modify. In phase two, we verified that GRAFCET programs can be successfully used to control complex continuous processes. An emergency sequence should be added to complete the process control. For future study, we recommend the use of the CADEPA for hydraulic and pneumatic applications. Furthermore, study can be done on the efficiency of the ladder logic generated by CADEPA versus conventional ladder logic.

INTRODUCTION

In this paper, we discuss our findings concerning the number of sequences with non-negative partial sums that can be formed from n 2's and k -1's. In particular, we give a recursive formula for computing the number of such sequences. We also derive a closed formula for the number of such sequences with $k = 2n$ and present some other findings for $2 \le k < 2n$.
Since these numbers which count our sequences can be evaluated in a manner similar to that of binomial coefficients, we will use a symbolism similar to that which is standard notation for the binomial coefficients.

Definition. Let $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$ denote the number of arrangements $a_1 a_2 \ldots a_{n+k}$ of n 2's and k -1's so that $a_1 + a_2 + \cdots + a_i \ge 0$ for all $1 \le i \le n+k$.
Example. Let us count the number of sequences with non-negative partial sums which can be formed from two 2's and four -1's. Clearly, we must begin with a 2. It is also clear that this initial 2 can be followed by no more than 2 -1's. Thus, there are 3 possible arrangments as shown below, and $\left\{\begin{matrix} 2 \\ 4 \end{matrix}\right\} = 3$.
#1 --- 2 2 -1 -1 -1 -1
#2 --- 2 -1 2 -1 -1 -1
#3 --- 2 -1 -1 2 -1 -1

PRINCIPAL RESULTS

Theorem 1.
(i) $\left\{\begin{matrix} n \\ 0 \end{matrix}\right\} = 1$ for $n \ge 1$.

(ii) $\left\{\begin{matrix} n \\ 1 \end{matrix}\right\} = n$ for $n \ge 1$.

(iii) $\left\{\begin{matrix} n+1 \\ k \end{matrix}\right\} = \left\{\begin{matrix} n+1 \\ k-1 \end{matrix}\right\} + \left\{\begin{matrix} n \\ k \end{matrix}\right\}$ for $1 < k < 2n+1$.

(iv) $\left\{\begin{matrix} n+1 \\ 2n+2 \end{matrix}\right\} = \left\{\begin{matrix} n+1 \\ 2n+1 \end{matrix}\right\} = \left\{\begin{matrix} n+1 \\ 2n \end{matrix}\right\}$ for $n \ge 0$.

Proof. Statement (i) is obvious by inspection. For statement (ii), notice that an arrangement of n 2's and a single -1 will occupy $n+1$ positions. But by the definition of the sequence, the fist position cannot be occupied by the -1. Thus, there are n such arrangements.

For statement (iii), imagine an arrangement of $n+1$ 2's and k -1's with $2 \le k < 2n+1$. The last element (a_{n+k+1}) is either a 2 or a -1. If it is a 2, then the remaining positions are filled with n 2's and k -1's. Hence, these positions can be filled in $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$ ways. On the other hand, if the last element is a -1, then the remaining positions are filled with $n+1$ 2's and k-1 -1's. This can be done in $\left\{\begin{matrix} n+1 \\ k-1 \end{matrix}\right\}$ ways. Thus, statement (iii) is established.

To establish statement (iv), we need to consider an arrangement of $n+1$ 2's and $2n+2$ -1's. Note that the last two elements in the arrangement must be -1's. Indeed, if either of these elements is a 2, then since $a_1 + a_2 + \cdots + a_{3n+1} + a_{3n+2} + a_{3n+3} = 0$ it must be the case that $a_1 + a_2 + \cdots + a_{3n+1} < 0$ which is contrary to our requirement. Hence, the first $3n+1$ positions are filled with $n+1$ 2's and $2n$ -1's. Thus the assertion of statement (iv) is valid.

Using the results of Theroem 1 we can construct a pseudo-triangular array containing the numbers $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$ in somewhat the same manner as the Pascal triangle is constructed. In particular, the nth row and the kth column will contain $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$. Each row begins with a 1 in the 0th column by part (i) of Theorem 1. The next entry (column 1) in the nth row will be n for $n \geq 1$ by part (ii). After that, part (iii) says that an element is determined by adding the element directly to the left and directly above until there are no elements directly above. (That is until we reach the $(2n-1)$th column of row n.) The final two entries of the row are obtained, by part (iv), by repeating the element immediately to the left.

Table 1: An Array Through Row 5

k=	0	1	2	3	4	5	6	7	8	9	10
n=1	1	1	1								
n=2	1	2	3	3	3						
n=3	1	3	6	9	12	12	12				
n=4	1	4	10	19	31	43	55	55	55		
n=5	1	5	15	34	65	108	163	218	273	273	273

We would like to produce a closed form for $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$ but have been able to do so only in certain special cases. One interesting case is $k=2n$. First, we need a preliminary definition and result.

Definition: A ternary tree is a finite set of elements that is either empty or partitioned into four disjoint subsets. The first subset is called the root, and the other three subsets are the left, middle, and right subtrees of the original tree. A left, middle, or right subtree can be empty. Each element of the ternary tree is called a node of the tree. [3]

It has been determined [2] that the number of different ternary trees that can be formed from n nodes is

$$\frac{1}{2n+1}\binom{3n}{n}. \tag{1}$$

Theorem 2.

There is a one-to-one correspondence between the sequences of n 2's and $2n$ -1's with non-negative partial sums and the ternary trees that can be constructed with n nodes. Thus,

$$\left\{\begin{matrix} n \\ 2n \end{matrix}\right\} = \frac{1}{2n+1}\binom{3n}{n}. \tag{2}$$

Proof. Before we begin to establish this correspondence, we need to expand a bit on the definition above. A ternary tree is constructed of nodes. There must always be at least one node, the root node. Each node can have at most three children but may have 0, 1, or 2. We let the nodes represent the positioning of the 2's in the sequence of 2's and -1's. That is, every non-empty node will represent a 2 and every empty node position will represent a -1. To translate from a ternary tree to a sequence, we start at the root node which represents a 2. Then we go to the next level. We read across the level from left to right. For every position possible stemming from the nodes in the previous level, there is either a node or an empty position. If there is a node in the position, we translate that to a 2; if the position is empty, we translate that to a -1. We read across the entire level before going to the next level. Once all the 2's have been accounted for (we have translated all the non-empty nodes), we add as many -1's as necessary to fill the sequence.

Now we translate from a sequence to a ternary tree as follows. We know that the first number in our sequence must be a 2 and this represents the root node of the ternary tree. Each node can have up to 3 child nodes. If the next number in the sequence is a 2, we put a node in the next child node position. Otherwise, we put an empty node in the next child node position. This continues across each level completely from left to right across all possible child nodes at that level before progressing to the next level. By constructing the ternary tree in this fashion until we run out of 2's in the sequence, we arrive at a ternary tree that is uniquely determined by the sequence.

As an example, let us consider $n=2$. We can see from the Table 1, that $\left\{\begin{matrix} 2 \\ 4 \end{matrix}\right\}=3$. The three results are presented in Figure 1.

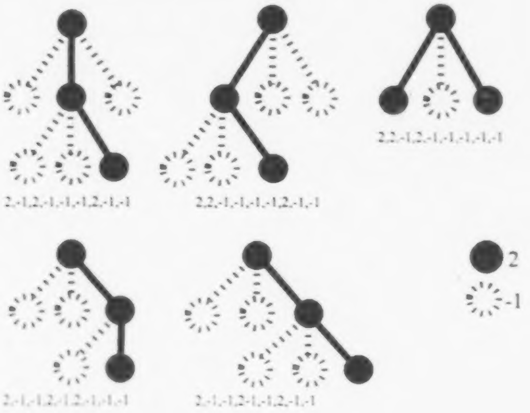

Figure 2

OBSERVATIONS
While we did not succeed in finding a closed form for $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$, we did make some interesting observations and derivations.

Lemma 1.

$$\left\{\begin{matrix} n \\ k \end{matrix}\right\} = \sum_{m=\left\lceil \frac{(k+1)}{2} \right\rceil}^{n} \left\{\begin{matrix} m \\ k-1 \end{matrix}\right\}. \qquad (3)$$

Proof. We will prove this lemma by induction on n.
Case 1: Suppose $k=2t+1$. Then the smallest value of n for which $\left\{\begin{matrix} n \\ k \end{matrix}\right\}$ is defined is $n=t+1$. Thus, our assertion is $\left\{\begin{matrix} t+1 \\ 2t+1 \end{matrix}\right\} = \sum_{m=\left\lceil \frac{(2t+2)}{2} \right\rceil}^{t+1} \left\{\begin{matrix} m \\ 2t \end{matrix}\right\}$. But this is simply $\left\{\begin{matrix} t+1 \\ 2t+1 \end{matrix}\right\} = \left\{\begin{matrix} t+1 \\ 2t \end{matrix}\right\}$ which we know to be true. So assume the result for some fixed $n>t+1$ and consider

$$\left\{\begin{matrix} n+1 \\ 2t+1 \end{matrix}\right\} = \left\{\begin{matrix} n+1 \\ 2t \end{matrix}\right\} + \left\{\begin{matrix} n \\ 2t+1 \end{matrix}\right\} = \left\{\begin{matrix} n+1 \\ 2t \end{matrix}\right\} + \sum_{m=\left\lceil \frac{(2t+2)}{2} \right\rceil}^{n} \left\{\begin{matrix} m \\ 2t \end{matrix}\right\} = \sum_{m=\left\lceil \frac{(2t+2)}{2} \right\rceil}^{n+1} \left\{\begin{matrix} m \\ 2t \end{matrix}\right\}.$$

Thus, the inductive step is complete and the result established.
Case 2: If $k=2t$, the argument is similar, and we do not present the details here.

For example, $\left\{{9 \atop 5}\right\}$ is the sum of all the terms in column 4 in rows 3 through 9.

Table 2: Lemma 1 Results

$$\left\{{n \atop 1}\right\} = \binom{n}{1}$$

$$\left\{{n \atop 2}\right\} = \binom{n+1}{2}$$

$$\left\{{n \atop 3}\right\} = \binom{n+2}{3} - \binom{n}{0}$$

$$\left\{{n \atop 4}\right\} = \binom{n+3}{4} - \binom{n}{1}$$

$$\left\{{n \atop 5}\right\} = \binom{n+4}{5} - \binom{n+1}{2} - 3\binom{n}{0}$$

$$\left\{{n \atop 6}\right\} = \binom{n+5}{6} - \binom{n+2}{3} - 3\binom{n}{1} + 3\binom{n}{0}$$

$$\left\{{n \atop 7}\right\} = \binom{n+6}{7} - \binom{n+3}{4} - 3\binom{n+1}{2} + 3\binom{n}{1} - 12\binom{n}{0}$$

$$\left\{{n \atop 8}\right\} = \binom{n+7}{8} - \binom{n+4}{5} - 3\binom{n+2}{3} + 3\binom{n+1}{2} - 12\binom{n}{1} + 24\binom{n}{0}$$

$$\left\{{n \atop 9}\right\} = \binom{n+8}{9} - \binom{n+5}{6} - 3\binom{n+3}{4} + 3\binom{n+2}{3} - 12\binom{n+1}{2} + 24\binom{n}{1} - 67\binom{n}{0}$$

$$\left\{{n \atop 10}\right\} = \binom{n+9}{10} - \binom{n+6}{7} - 3\binom{n+4}{5} + 3\binom{n+3}{4} - 12\binom{n+2}{3} + 24\binom{n+1}{2} - 67\binom{n}{1} + 165\binom{n}{0}$$

$$\left\{{n \atop 11}\right\} = \binom{n+10}{11} - \binom{n+7}{8} - 3\binom{n+5}{6} + 3\binom{n+4}{5} - 12\binom{n+3}{4} + 24\binom{n+2}{3} - 67\binom{n+1}{2} + 165\binom{n}{1} - 438\binom{n}{0}$$

$$\left\{{n \atop 12}\right\} = \binom{n+11}{12} - \binom{n+8}{9} - 3\binom{n+6}{7} + 3\binom{n+5}{6} - 12\binom{n+4}{5} + 24\binom{n+3}{4} - 67\binom{n+2}{3} + 165\binom{n+1}{2} - 438n + 1147$$

As an example of these derivations, let us derive the formula above for $\left\{{n \atop 3}\right\}$:

$$\left\{{n \atop 3}\right\} = \sum_{k=1}^{n} \left\{{k \atop 2}\right\} = \sum_{k=1}^{n} \frac{k(k+1)}{2} = \frac{1}{2}\sum_{k=2}^{n} (k^2+k) = \frac{1}{2}\left[\sum_{k=1}^{n} (k^2+k) - 2\right] = \tag{4}$$

$$\frac{1}{2}\left[\frac{n(n+1)(2n+1)}{6} + \frac{n(n+1)}{2} - 2\right] = \frac{n(n+1)(n+2)}{6} - 1 = \binom{n+2}{3} - \binom{n}{0}$$

It is clear that there is a great deal of structure in the arrary above. One immediately sees that

$$\left\{{n \atop k}\right\} = \binom{n+k-1}{k} - \binom{n+k-4}{k-3} + \sum_{i=1}^{k-3} a_i \binom{n+k-4-i}{k-3-i} \tag{5}$$

It is also clear that the sequence of a's begins -3,3,-12,24,-67,165,-438,1147,...
What is not clear is how one generates this sequence of a's.

FURTHER OBSERVATIONS

We know each of the diagonal entries, and we know that each entry is the difference of the term immediately to the right and the term immediately above and to the right. This observation can be used to compute $\left\{{n \atop k}\right\}$ in several special cases. In particular, we have:

Table 3: Some Results

$$\left\{ {n \atop 2n} \right\} = \left\{ {n \atop 2n-1} \right\} = \left\{ {n \atop 2n-2} \right\} = \frac{1}{2n+1}\binom{3n}{n}$$

$$\left\{ {n \atop 2n-3} \right\} = \binom{3n-3}{n-1}\frac{23n^2-29n+6}{(2n+1)(2n)(2n-1)}$$

$$\left\{ {n \atop 2n-4} \right\} = \binom{3n-3}{n-1}\frac{19n^2-31n+6}{(2n+1)(2n)(2n-1)}$$

$$\left\{ {n \atop 2n-5} \right\} = \binom{3n-3}{n-1}\frac{15n^2-33n+6}{(2n+1)(2n)(2n-1)}$$

$$\left\{ {n \atop 2n-6} \right\} = \binom{3n-6}{n-2}\frac{313n^4-1852n^3+3653n^2-2582n+360}{(2n+1)(2n)(2n-1)(2n-2)(2n-3)}$$

$$\left\{ {n \atop 2n-7} \right\} = \binom{3n-6}{n-2}\frac{237n^4-1614n^3+3567n^2-2694n+360}{(2n+1)(2n)(2n-1)(2n-2)(2n-3)}$$

$$\left\{ {n \atop 2n-8} \right\} = \binom{3n-6}{n-2}\frac{177n^4-1392n^3+3477n^2-2802n+360}{(2n+1)(2n)(2n-1)(2n-2)(2n-3)}$$

As an example of these derivations, let us derive the formula above for $\left\{ {n \atop 2n-3} \right\}$:

$$\left\{ {n \atop 2n-3} \right\} = \left\{ {n \atop 2n-2} \right\} - \left\{ {n-1 \atop 2n-2} \right\} = \left\{ {n \atop 2n} \right\} - \left\{ {n-1 \atop 2n-2} \right\} = \frac{1}{2n+1}\binom{3n}{n} - \frac{1}{2n-1}\binom{3(n-1)}{n-1} =$$

$$\frac{1}{2n+1}\frac{(3n)!}{n!(2n)!} - \frac{1}{2n-1}\frac{(3n-3)!}{(n-1)!(2n-2)!} = \frac{(3n-3)!}{(n-1)!(2n-2)!}\left[\frac{1}{2n+1}\frac{(3n)(3n-1)(3n-2)}{n(2n-1)(2n)} - \frac{1}{2n-1}\right] =$$

$$\frac{1}{2n-1}\binom{3n-3}{n-1}\left[\frac{3(9n^2-9n+2)-(2n)(2n+1)}{2n(2n+1)}\right] = \binom{3n-3}{n-1}\frac{23n^2-29n+6}{(2n+1)(2n)(2n-1)} \tag{6}$$

CONJECTURE

Technically, we have let $\left\{ {n \atop k} \right\}$ really represent $\left\{ {n \atop k} \right\}_2$. Based on the results found here and the previous research done on 1's and -1's by Bailey [1], we present the following conjecture for $\left\{ {n \atop mn} \right\}_m$, the number of sequences with non-negative parital sums formed from n m's and mn -1's where m is any positive integer:

$$\left\{ {n \atop mn} \right\}_m = \frac{1}{mn+1}\binom{(m+1)n}{n} \tag{7}$$

Magic Squares as Matrices

April Warn

Department of Mathematics
Trinity University
715 Stadium Drive
San Antonio, TX 78212

Faculty Advisor:

Dr. Donald Bailey

A magic square is an n x n array of integers in which the entries in each row, column, and diagonal sum to the same number. We call a magic square traditional if the n^2 entries are simply the numbers 1, 2, ..., n^2. A magic square can be regarded as a matrix, and so we may examine its linear algebraic properties. We originally conjectured that an n x n traditional magic square is singular if n is even. Although we were able to establish this result for certain special cases, the conjecture is false in general.

SOME PRELIMINARY RESULTS

There are some previously established properties of magic squares that we will use (cf. Andrews). The first of these properties concerns the common sum of the rows, columns, and diagonals. This number is called the magic number of the square and will be denoted by S. In the case of the traditional magic square, we can arrive at a formula for S. The sum of all the entries in the traditional magic square is

$$\sum_{i=1}^{n^2} i = \frac{n^2(n^2+1)}{2}$$

This sum must be distributed equally across the n rows of the square, so we have that, in the traditional magic square,

$$S = \frac{n^2(n^2+1)}{2n} = \frac{n(n^2+1)}{2}$$

Second, viewing a magic square as an n x n matrix, we see that S is an eigenvalue of the square corresponding to the eigenvector $(1, 1, ..., 1)^T$. The magic square has n (not necessarily distinct) eigenvalues, and the next result states some properties of the eigenvalues different from S and their corresponding eigenvectors.

Theorem 1: If $\lambda \neq S$ is an eigenvalue of a magic square A with corresponding eigenvector $(x_1, x_2, \ldots, x_n)^T$, then $\sum_{i=1}^{n} x_i = 0$.

Proof: Let

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

Since λ is an eigenvalue of A corresponding to $(x_1, x_2, \ldots, x_n)^T$, we have that

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n &= \lambda x_1 \\ a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n &= \lambda x_2 \\ &\ldots \\ a_{n1}x_1 + a_{n2}x_2 + \ldots + a_{nn}x_n &= \lambda x_n \end{aligned}$$

Adding these equations, we find

$$(a_{11} + a_{21} + \ldots + a_{n1})x_1 + (a_{12} + a_{22} + \ldots + a_{n2})x_2 + \ldots + (a_{1n} + a_{2n} + \ldots + a_{nn})x_n = \lambda(x_1 + x_2 + \ldots + x_n) \Rightarrow$$
$$Sx_1 + Sx_2 + \ldots + Sx_n = \lambda(x_1 + x_2 + \ldots + x_n) \Rightarrow (S - \lambda)(x_1 + x_2 + \ldots + x_n) = 0$$

Since $S \neq \lambda$, $x_1 + x_2 + \ldots + x_n = 0$. □

REGULAR MAGIC SQUARES

A regular magic square is a magic square in which entries diametrically opposite the center sum to $\frac{2}{n}S$ (cf. Andrews 1). For example,

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ & & & \\ a_{n1} & a_{n2} & & a_{nn} \end{bmatrix}$$

is an n x n regular magic square if and only if $a_{11} + a_{nn} = a_{21} + a_{n-1,n} = \ldots = a_{ij} + a_{n-i+1,n-j+1} = \frac{2}{n}S$. As a concrete example,

$$\begin{bmatrix} 1 & 12 & 14 & 7 \\ 8 & 13 & 11 & 2 \\ 15 & 6 & 4 & 9 \\ 10 & 3 & 5 & 16 \end{bmatrix}$$

is a 4 x 4 regular magic square, since $a_{11} + a_{44} = a_{12} + a_{43} = \ldots = 17$.

In attempting to prove our conjecture, we first examined this special type of magic square, and arrived at the following result.

Theorem 2: If A is an n x n regular magic square and $\lambda \neq S$ is an eigenvalue of A corresponding to the eigenvector $(x_1, x_2, x_3, \ldots, x_n)^T$, then $-\lambda$ is an eigenvalue of A corresponding to the eigenvector $(x_n, \ldots, x_3, x_2, x_1)^T$.

Proof: Let

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

be an n x n regular magic square. By Theorem 1, $x_1 + x_2 + x_3 + \ldots + x_n = 0$, so certainly $\frac{2}{n}S(x_1 + x_2 + x_3 + \ldots + x_n) = 0$. This implies that $(a_{11} + a_{nn})x_1 + (a_{12} + a_{n,n-1})x_2 + \ldots + (a_{1n} + a_{n1})x_n = 0$ which in turn implies that $a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n = -(a_{nn}x_1 + a_{n,n-1}x_2 + \ldots + a_{n1}x_n)$. Since $(x_1, x_2, x_3, \ldots, x_n)^T$ is an eigenvector of A, $a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n = -(a_{nn}x_1 + a_{n,n-1}x_2 + \ldots + a_{n1}x_n) = \lambda x_1$. Thus $a_{n1}x_n + \ldots + a_{n,n-1}x_2 + a_{nn}x_1 = -\lambda x_1$. In a similar manner, one can show that

$$a_{n-1,1}x_n + \ldots + a_{n-1,n-1}x_2 + a_{n-1,n}x_1 = -\lambda x_2$$

$$\ldots$$

$$a_{11}x_n + \ldots + a_{1,n-1}x_2 + a_{1n}x_1 = -\lambda x_n$$

Equivalently, $-\lambda$ is an eigenvalue of A corresponding to $(x_n, \ldots, x_3, x_2, x_1)^T$. □

Corollary: A 4 x 4 regular magic square is singular.

Proof: Let

$$A = \begin{bmatrix} a & b & c & d \\ e & f & g & h \\ i & j & k & l \\ m & n & o & p \end{bmatrix}$$

be a 4 x 4 regular magic square. A has four (not necessarily distinct) eigenvalues. Call these eigenvalues λ_1, λ_2, λ_3, and λ_4. We may assume that $\lambda_1 = S$. Also, from linear algebra, we know that $\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = \text{trace}(A) = a + f + k + p = S$ (cf. Leon). Therefore, $\lambda_2 + \lambda_3 + \lambda_4 = 0$. This implies that at least one of λ_2, λ_3, $\lambda_4 \neq S$; assume $\lambda_2 \neq S$. If $\lambda_2 = 0$, we have proved the result, since a matrix with a zero eigenvalue is singular. So assume $\lambda_2 \neq 0$. Then, by Theorem 2, $-\lambda_2$ is an eigenvalue of A; let $\lambda_3 = -\lambda_2$. So $\lambda_2 + \lambda_3 = 0$, which implies that $\lambda_4 = 0$. Therefore, A must have a zero eigenvalue; hence A is singular. □

SYMMETRIC MAGIC SQUARES

The next special case we consider is the symmetric magic square. This is a square in which the pairs of numbers summing to $\frac{2}{n}S$ "are arranged symmetrically in relation to a perpendicular line through the center of the square" (cf. Frierson 140). So,

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

is an n x n symmetric magic square if and only if
$a_{11} + a_{1n} = a_{12} + a_{1,n-1} = \ldots = a_{ij} + a_{i,n-j+1} = \frac{2}{n}S$. As an example,

$$A = \begin{bmatrix} 1 & 11 & 6 & 16 \\ 14 & 3 & 4 & 3 \\ 7 & 2 & 15 & 10 \\ 12 & 8 & 9 & 5 \end{bmatrix}$$

is a 4 x 4 symmetric magic square. Notice that a symmetric magic square cannot be regular.

It is easy to see that such a square must be singular. Consider the 4 x 4 case; the eigenvector $(1, -1, -1, 1)^T$ will correspond to a zero eigenvalue.

In fact, the condition of symmetry may be relaxed somewhat and the magic square will remain singular; it is only necessary that the pairs of numbers summing to $\frac{2}{n}S$ be consistently arranged over each row in the square. For example, any 4 x 4 traditional magic square in which the "17-pairs" (i.e. 1 and 16, 3 and 14, etc.) are arranged in the same pattern in each row will necessarily be singular:

$$\begin{bmatrix} a & 17-a & b & 17-b \\ c & 17-c & d & 17-d \\ e & 17-e & f & 17-f \\ g & 17-g & h & 17-h \end{bmatrix} \quad (1, 1, -1, -1)^T \text{ corresponds to } \lambda = 0$$

$$\begin{bmatrix} a & b & 17-a & 17-b \\ c & d & 17-c & 17-d \\ e & f & 17-e & 17-f \\ g & h & 17-g & 17-h \end{bmatrix} \quad (1, -1, 1, -1)^T \text{ corresponds to } \lambda = 0$$

This reasoning can be generalized to establish

Theorem 3: An n x n magic square in which the "$\frac{2}{n}S$ pairs" are arranged in a consistent pattern over each row is singular.

For example,

$$A = \begin{bmatrix} 16 & 1 & 4 & 13 \\ 10 & 7 & 6 & 11 \\ 5 & 12 & 9 & 8 \\ 3 & 14 & 15 & 2 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 16 & 13 & 1 & 4 \\ 3 & 2 & 14 & 15 \\ 10 & 11 & 7 & 6 \\ 5 & 8 & 12 & 9 \end{bmatrix}$$

are both singular matrices. Also, since in general $\det(A) = \det(A^T)$, the occurrence of any of the above patterns in the columns of the square guarantees singularity.

By looking for variations in the patterns of the "17-pairs," we were able to resolve the conjecture for the 4 x 4 case. For example, what happens if every entry occurs in the same row as its "17-complement," but there is no consistent arrangement of these pairs over every row? Consider

$$A = \begin{bmatrix} 1 & 16 & 13 & 4 \\ 6 & 9 & 8 & 11 \\ 12 & 7 & 10 & 5 \\ 15 & 2 & 3 & 14 \end{bmatrix}$$

which has determinant 3264, thus disproving the conjecture.

CONCLUSIONS

Our original conjecture is not true in the 4 x 4 case; therefore it seems reasonable to believe that an arbitrary n x n magic square is not necessarily singular when n is even. However, we speculate that a regular magic square of any even dimension is singular. Certainly Theorem 2 holds; the only problem to resolve is the multiplicity of the eigenvalues, i.e. if λ and $-\lambda$ are eigenvalues of the square, it is not clear that they must have the same multiplicity. If they do not, the n eigenvalues could possibly sum to S while none of the eigenvalues is zero.

The segmented reflector test-bed is an experimental apparatus that is designed and developed at the Control and Structures Research Laboratory (CSRL) at California State University, Los Angeles. The test-bed is capable of performing experiments that simulate the complex dynamic of a large segmented optical system. It is a generic experimental facility that can address in an integrated way the problems associated with Control and Structure Interaction (CSI), distributed control of multi-input multi-output systems, optics, electronics, actuator and sensor design, and digital implementation. It is specifically designed to demonstrate, in a unique way, the advantages of decentralized control approach to large scale systems.

BACKGROUND

Future astronomical space missions will require high-performance optical systems. Such optical systems will necessarily have large apertures for high-precision performance making the size of the reflectors very large. Due to practical considerations such as time, cost and complexity of fabricating large-apertures telescopes, as well launch vehicle size, weight and power constrains, future telescopes will be made of precision-segmented reflectors. A segmented mirror reflector consists of mirror panels which, when formed together, become a parabolic primary mirror that magnify the images from space. These mirror panels are easily manufactured, and deployable in space.

With the advantages of the segmented reflector telescopes, shortcoming are also presented. The large size of these telescopes make the structure flexible to external forces such as thermal fluctuations and solar disturbances. It becomes apparent that development of control concepts and extensive performance evaluation via simulation in an environment characterized by various dynamic disturbances is a necessity. The control design challenge is to make the segmented reflector perform as a monolithic reflector. This is done via high-precision figure control which would maintain the surface of the reflector to within a specified tolerance of the calibrated reference position.

THE STRUCTURE AND COMPONENTS DESIGN

Overall Structure And Components design

The C.S.R.L. test-bed consists of several major components actuator platforms, mirror segments, truss members, fittings and joint flexures.

SEGMENTED PRIMARY MIRROR

The CSRL primary mirror is designed to emulate the critical properties of a real segmented mirror. These properties include segmentation geometry, inter-segment spacing, segment mass, inertia and stiffness, and optical focal ratio (H.Boussalis, M. Mirmirani and Z. Wei, 1995). The seven segment primary mirror consists of a ring of six actively controlled hexagonal segments surrounding a fixed center segment that acts as a reference. Because the test-bed is control-system oriented, and because of difficulty and added expense of fabrication of actual optical-quality segments made from glass, the segments will be fabricated from flat honeycomb aluminum plates. The active segments are attached to segment-positioning actuators with special three-degree-of-freedom flexures. These flexures permit individual segments to have two rotational degree of freedom (tilt) and one transitional degree of freedom (piston). Each segments is controlled by three actuators and the entire primary has a total of 18 actuators. Figure 1 illustrates the isometric view of a flexure and a schematic diagram of the special arrangements of three flexures to a mirror segment, resulting in three degrees of freedom motion. The relative displacement between the edges of adjacent segment is measure by an ensemble of 24 edge sensors. The edge sensors provide information about a segment's relative displacement as well as absolute displacements from the fixed center reference segment.

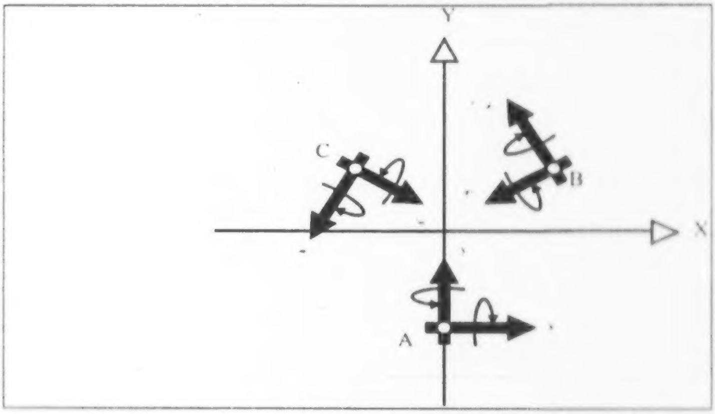

Figure 1: Orientation of Joint Flexure with Respect to Panel

STRUCTURE

One of the most fundamental design goals has been a strong, light-weight truss structure whose structural-dynamic characteristics are representative of a large, flexible space-borne system. These include low frequency modes, high modal density and global mode shapes that properly reflect the coupling of the sub-elements of the structure. therefore, the requirements for the design of the truss, in addition to the dimensional constrains, has been a careful trade-off between the need for the structure to support itself in the 1-g laboratory environment versus the need to keep the frequency of the first mode as low as possible. We employed multi-criteria optimization technique based on Pareto-optimality concept to accomplish this objective (Guyan, W.B.,1990). We used CADKEY and AUTOCAD software to create a baseline primary truss structure. The baseline design consists exclusively of tetrahedrons with 60 elements and 21 nodes as shown in Figure 2.

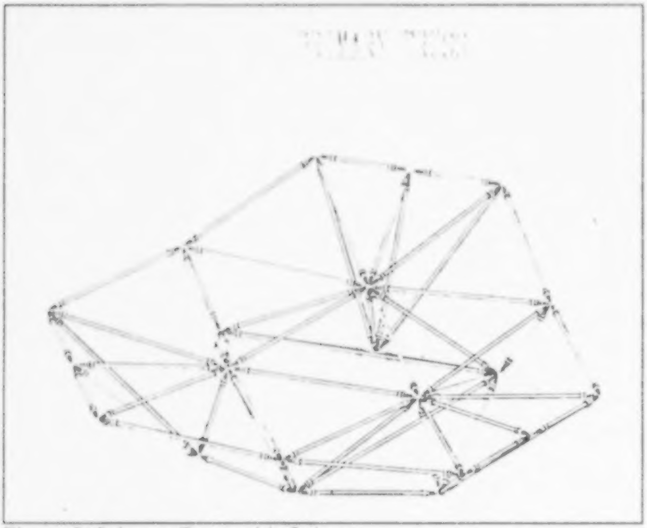

Figure 2: Primary Truss with fittings

THE ELECTRONIC AND COMPUTER ARCHITECTURE

Overall Electronic and Computer Architecture

The drive electronics used in the C.S.R.L. testbed is for the purpose of processing the analog output of sensors and interfacing with the segment position actuators. The drive electronics is in charge of real-time processing and data acquisition. The computer and graphic set up includes a DSP, a PC and two SUN stations. The Digital Signal Processor is the main computational unit and it is responsible for real-time control processing, signal generation, and real-time directory memory. The DSP and the SUN stations are used to monitor the C.S.R.L. experiments via the graphical display of the Kaman sensor reading, the actuator commands, and the mirror segments piston. The input/output unit is composed of two 32-channels 16-bit analog-to-digital converters.

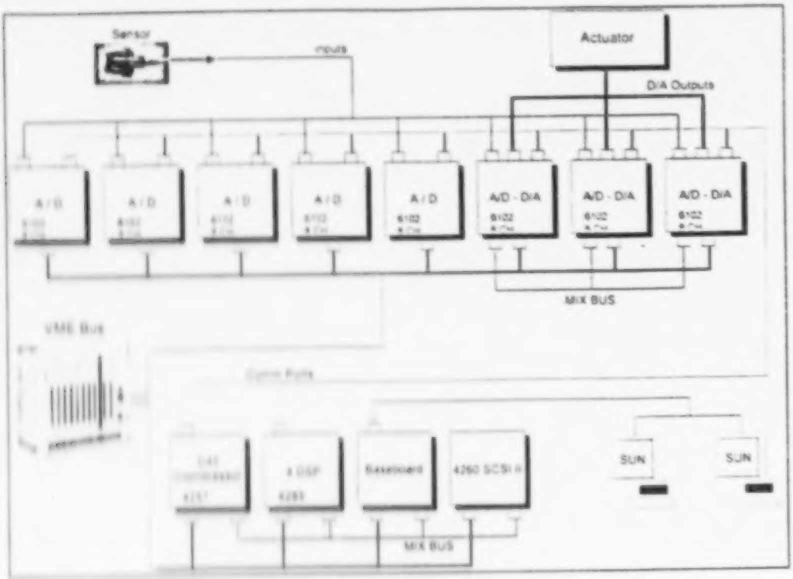

Figure 3: Block Diagram of Electronic and Computer Architecture

Sensors

The primary mirror of the Segmented Reflector Telescope consists of seven hexagonal panels with the center one fixed. A total of 24 edge sensors are distributed on the 12 adjacent edges between panels (2 for each edge). Each sensor is able to detect displacement or misalignment of adjacent panels when the telescope is subjected to any disturbance (Carrier, 1990). The sensors interface with the analog-to-digital converter, so that the output of the sensor can be transmitted to the controlling unit digitally. The sensors are the only components of the electronic system involved in the measurement, conversion, and transmission of data back to the controllers. Sensors must be used to measure the position of the segments with respect to some unique, stable reference rather than with respect to the underlying structure. This is accomplished by the edge sensors, whose output will guide the controllers to re-align the panels to attain a parabolic shape. A control fixed segment is chosen as a reference for the whole system and the position on individual segments are obtained by a special algorithm that applies to proper geometric transformation to the ensemble of sensor signal. With a 100,000 dynamic range, a resolution of 1 μm, an accuracy of 1 micron, and a voltage range of +/- 10 volts, the linear inductive proximity sensors (model 6U1) are one of the fastest and more accurate types of sensors, which will be used for panel displacement monitoring.

A/D and D/A Converters

The purpose of the analog-to-digital converters is to receive an analog voltage, producing a corresponding binary output which is proportional to the analog input. Such an input in our case is the analog output voltage of the edge position sensors. A 64-channel A/D converter with 16-bit resolution, differential amplifier inputs, voltage range of +/10 volts, and a minimum sampling rate (for aliasing prevention) of 320 KHz is required for proper sensor output sampling and conversion. These requirements also apply for the digital to analog converter, whose purpose is to convert the processed signal back into an analog

113

voltage for use in actuator triggering.

The DSP Board

Once an analog signal has been converted to digital form, operations can be performed on the data in the Digital Signal Processor by means of a programmable set of instructions. The DSP acts as the brain of the electronics control unit, using high-speed CPUs to analyze and process the incoming digital data, and process a digital output code that will be used (after D/A conversion) to correct panel positions. A 40 MFLOP (million of floating-point math operations per second) DSP, with direct memory access, and VME Bus compatibility is used in the C.S.R.L. electronics control systems.

The VME Bus

The transferring of data within the electronic control system is provided by the VME Bus (Versa Module Eurocard Bus). It is a standard chassis consisting of one or more master and slave modules. The master modules are employed for processor boards, while slave modules are memory and I/O boards (Peterson 1992). The VME Bus is used for the transfer of data within components at speeds of up to 80 Mbytes per second.

CONCLUSION

The test-bed has being designed to perform the essential functions needed for the various system missions. Performance of the test-bed is expected to be of comparable quality to that of an actual optical system. All these has been achieved through the design of the several mechanical components, the electronic control system, decentralized control algorithms

In recent years, aluminum copper lithium alloys have been used in high performance commercial and military aircraft due to its improved strength, high stiffness, low density, high modulus, and high temperature capability. In this experiment, tests were conducted on specimens of Al-Cu-Li (2195) alloy to observe changes in the tensile properties of the alloy due to the combined stretching and aging processes. After being solution-treated at 510 °C for one hour, the alloys were immediately quenched and stretched parallel to rolling direction of the plate to approximately 5%, 10%, and 15% plastic strain, followed by aging at 180 °C for 24 hours. The plates were cut into tensile specimens according to ASTM specifications for testing on the MTS 810 System with Teststar Software to determine the effect of stretching on the tensile properties of the Al-Cu-Li (2195) alloy.

INTRODUCTION

The 2195 alloy is planned to be primarily used for the external liquid-fuel tank in the space shuttle due to its excellent cryogenic mechanical properties (Frazier, Lee, Donnelian, and Thompson, 1989). Other important properties of the 2195 alloy are its low density, high modulus of elasticity, and fatigue toughness properties. The Al-Li alloy was selected over conventional high strength alloys because of its high temperature capabilities, and resistance to fatigue crack propagation (Lee and Frazier, 1988). The 2195 alloy offers improved density and strength over the 2219 (Al-Cu-Mn) alloy with comparable strength and weldabiltiy.

Aluminum lithium alloys containing copper need to be stretched prior to aging in order to obtain optimal strength and fracture toughness (Lee and Frazier, 1988). Al-Li alloys having 2wt % Cu and T_1 precipitates are significantly affected by stretching. The formation of the precipitates increases the amount of dislocations thus increasing the strength of the alloy.

Aluminum alloys including Al-Cu-Li alloy are strengthened by age hardening (precipitate hardening). The strengthening effect is due to the formation of coherent precipitates which act as the strengthening phase. In the process of solution treatment at 510 °C, all precipitates are dissolved. After the alloy is changed from two phases to one phase (Al solid solution α), the alloy is immediately quenched in water to prevent the formation of coarse precipitates. After quenching, the alloy is aged at 180 °C. During the aging process, fine precipitates nucleate and grow from the supersaturated α phase. These fine coherent precipitates strengthen the Al alloy (Flinn and Trojan, 1990). In the current study, the pre-stretching and age hardening processes are demonstrated using Al-Cu-Li (2195) alloy.

EXPERIMENTAL PROCEDURE

The Al-Cu-Li (2195) alloy plate used in this study was supplied by Lockheed-Martin in New Orleans, Louisiana. Placing the plates in the Sybron Thermolyne Furnace with Furnatrol III Type 19300 Automatic Controller, the plates were solution-treated at 510 °C for 1 hour followed by quenching in water as shown in Figure 1. Using the Material Testing System 810 with Teststar software (MTS 810), the plates were then stretched uniaxially 5%, 10%, and 15% in the rolling directions. The plates were placed in furnace at 180 °C to heat for 24 hours to evaluate the effects of artificially aging. Using the International Electronics Co., Ltd. TensilKut with Type 33 electronic motor control, tensile specimens were cut in the rolling and transverse directions The tensile specimens were prepared in accordance with ASTM standards with a gage length of 2.0 inches, width of 0.5 inches and nominal thickness of 0.25 inches Using the MTS 810, the specimens were tested to determine changes in the tensile properties such as yield strength, and ultimate tensile strength The results of the test were recorded and compared with previous test to examine significant change in the properties

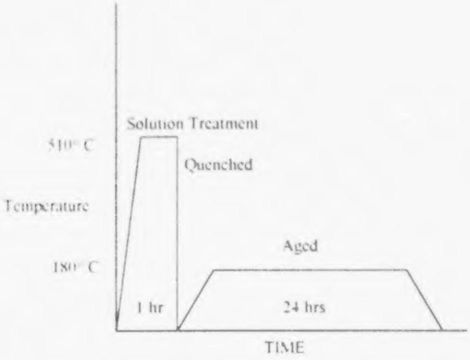

Figure 1 Procedures for age hardening heat treatment

DISCUSSIONS AND RESULTS

When Al-Cu-Li alloy is stretched, the yield strength and ultimate tensile strength increase The change in strength is dependent upon the amount of stretching and orientation of the specimen to grain upon cutting The yield strength and ultimate tensile strength in the 90° stretched 6% exceeds 80 ksi and 85 ksi, respectively in all orientations (Es-Said and Lee, 1995)

In this experiment, the Al-Cu-Li alloy plates were stretched various percentages along the rolling direction To evaluate the best direction to apply, specimens were tested in the rolling and transverse (90°) direction The yield strength and ultimate tensile strenght for each specimen was determined from the stress-strain curves and data tables with the average value being taken as the result In the rolling direction, the yield strength and ultimate tensile strength exceed 76 ksi and 82 ksi respectively for 5% stretching, 81 ksi and 87 ksi respectively for 10% stretching, and 82 ksi and 88 ksi respectively for 15% stretching In the transverse direction, the yield strength and ultimate tensile strength exceed 76 ksi and 81 ksi respectively for 5% stretching, 79 ksi and 84 ksi respectively for 10% stretching, and 78 ksi and 83 ksi respectively for 15% stretching The comparison plots in figure 2 indicates the maximum value for yield strength and ultimate tensile strength for the alloy cut in transverse and rolling directions The rolling direction yield strength and ultimate tensile strength exceeded thoses in the transverse direction The 15% stretching exceeded the 5% and 10% stretching The best process for the application of the alloy is 15% stretched rolling direction artificially aged

TABLE 1 Average Yield Strength and Ultimate Tensile Strength Of Al-Cu-Li (2195) Alloy In Artificially Aged Condition Cut In Rolling and Transverse Direction With Stretching In the Rolling Direction

Stretching	Rolling	Transverse	Rolling	Transverse
(%)	Yield Strength (psi)		Ultimate Tensile Strenght (psi)	
5	76241.5	76070.8	82677.0	81745.3
10	81395.0	79466.4	87526.0	84044.5
15	82967.5	78069.5	88649.0	83323.5

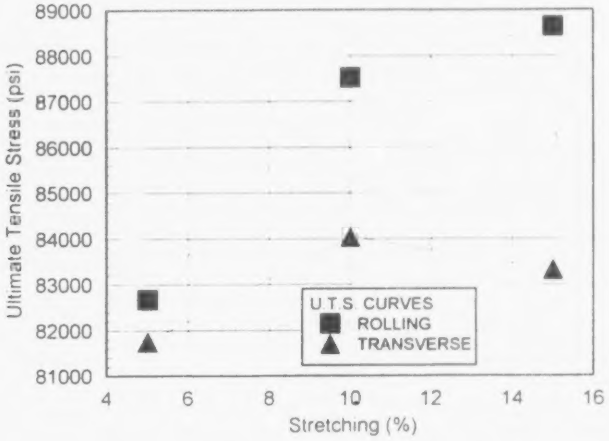

Figure 3. ULTIMATE TENSILE STRENGTH AS A FUNCTION OF STRETCHING PRIOR TO AGING

1141

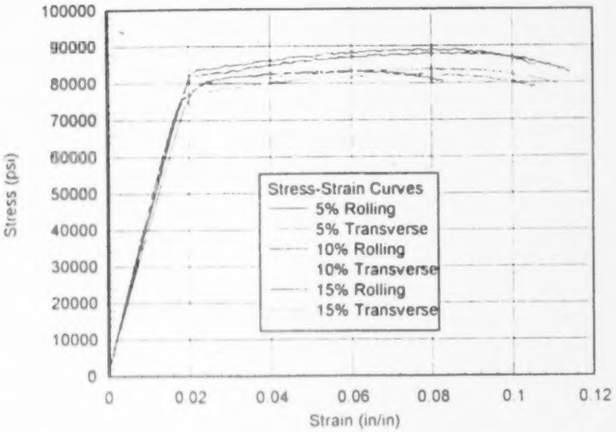

Figure 4. Pre-stretched Artificially Aged Specimens Stress-Strain Curves

CONCLUSIONS

1. The degree of stretching and direction has an effect on the yield strength and ultimate tensile strength.
2. The maximum yield strength and ultimate tensile strength for a 15% rolling direction stretched artificially aged specimen is 82 ksi and 88 ksi respectively.

Resolvents of m-Accretive Operators in Banach spaces

Eric Lehr

Collegium of Natural Sciences
Eckerd College
4200 - 54th Avenue South
St. Petersburg, FL 33711

Faculty Advisor:

Dr. David Kerr

In this paper, a "resolvent identity" for the m-accretive operator T is developed. A number of theorems concerning these resolvents are proven and in particular, their uniform convergence to the identity operator is demonstrated.

INTRODUCTION

Accretive operators were first introduced in 1962 by George Minty [8] and have since been extensively studied by Barbu [1], Browder [2], Deimling [3], Kartsatos [5], Lakshmikantham and Leela [7]. These operators have achieved some noteriety in applications involving solutions to partial-differential equations as well as to ordinary differential equations and integro-differential equations.

In this paper, accretive operators are explored from an abstract point of view. First, a result will be proven to establish the equivalency of two well-known definitions of "m-accretiveness". These definitions were initially proposed by George Minty and by Tosio Kato [6] respectively.

Some properties of the "resolvent operators" will be developed and it will be proven that not only do the resolvents converge pointwise to the identity, but that this convergence is uniform. In proving this last result a variation of a "resolvent identity" which was initially developed by Guan and Kartsatos [4] will be established.

ACCRETIVE OPERATORS

The operator T: $D(T) \subset X \rightarrow X$, where X is a Banach space, is accretive if $\forall\, n \in N$ and $\forall\, x, y \in D(T)$ the following inequality holds:

$$\|x - y\| \leq \|x - y + \frac{1}{n}(T(x) - T(y))\| \qquad (1)$$

An accretive operator T is said to be m-accretive if

$$R(T + \frac{1}{n}I) = X \quad \forall\, n \in N \qquad (2)$$

Some examples of accretive operators are:

1. Any increasing function from $R \rightarrow R$
2. Any positive definate matrix in R^n.
3. Negative the Laplacian $\left(-\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2}\right)$

The definitions of accretive and m-accretive, equations (1) and (2), were established by Tosio Kato in 1967. Five years earlier, George Minty defined an accretive operator to be m-accretive if $R(I + T) = X$, which is similar to Kato's definition with $n \equiv 1$. The following theorem demonstrates that Minty's definition implies Kato's.

BEST COPY AVAILABLE

Theorem 1: Let $T: D(T) \subset X \to X$ be an accretive operator.
If $R(I + T) = X$ then $R(I + nT) = X \ \forall n \in N$.

Proof: Suppose that T is accretive with $R(I + T) = X$. Let $y \in X$ and $n \in N$. Then the equation $(I + nT)x = y$ is equivalent to the equation,

$$x = (I + T)^{-1}\left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x\right). \tag{3}$$

To see this, consider

$$\begin{aligned}
(I + nT)x &= y \\
\left(\frac{1}{n} I + T\right)x &= \frac{y}{n} \\
T(x) &= \frac{y}{n} - \frac{1}{n}x \\
x + T(x) &= \frac{y}{n} + x - \frac{1}{n}x \\
(I + T)x &= \frac{y}{n} + \left(1 - \frac{1}{n}\right)x \\
x &= (I + T)^{-1}\left[\frac{y}{n} + \left(1 - \frac{1}{n}\right)x\right].
\end{aligned}$$

As will be shown in the next section, the operator $(I + T)^{-1}$ is non-expansive, so the operator $(I + T)^{-1}\left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x\right)$ is Lipschitz continuous. Indeed,

$$\begin{aligned}
&\left\|(I + T)^{-1}\left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x_1\right) - (I + T)^{-1}\left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x_2\right)\right\| \\
&\leq \left\|\left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x_1 - \left(\frac{y}{n} + \left(1 - \frac{1}{n}\right)x_2\right)\right\| \\
&\leq \left\|\left(1 - \frac{1}{n}\right)x_1 - \left(1 - \frac{1}{n}\right)x_2\right\| \\
&= \left|1 - \frac{1}{n}\right| \, \|x_1 - x_2\|.
\end{aligned}$$

Therefore, the Lipschitz constant is $\left|1 - \frac{1}{n}\right|$ and by the fixed point contraction theorem, equation (3) has a unique solution. This result implies that $(I + nT)x = y$ has a solution, which implies that $R(I + nT) = X$ since y was an arbitrary element of X.

Clearly, $R(I + nT) = X$ implies that the operator $n(T + \frac{1}{n}I)$ is onto.

Thus, $R(T + \frac{1}{n}I) = X$.

RESOLVENTS OF m-ACCRETIVE OPERATORS

T accretive implies $\left\|x - y + \frac{1}{n}(T(x) - T(y))\right\| \geq \|x - y\|$ which implies $\left\|(x + \frac{1}{n}T(x)) - (y + \frac{1}{n}T(y))\right\| \geq \|x - y\|$ so if $(I + \frac{1}{n}T)(x) = (I + \frac{1}{n}T)(y)$ then $x = y$. Thus $(I + \frac{1}{n}T)$ is one-to-one, which implies $(I + \frac{1}{n}T)^{-1}$ exists. Now let $u = x + \frac{1}{n}T(x)$ and $v = y + \frac{1}{n}T(y)$ for some $x, y \in D(T)$ and $n \in N$,

BEST COPY AVAILABLE

then

$$\begin{aligned}\|u - v\| &= \|x + \frac{1}{n}T(x) - (y + \frac{1}{n}T(y))\| \\ &= \|x - y + \frac{1}{n}(T(x) - T(y))\| \\ &\geq \|x - y\| \\ &= \|(I + \frac{1}{n}T)^{-1}u - (I + \frac{1}{n}T)^{-1}v\|.\end{aligned}$$

Therefore, the operator $(I + \frac{1}{n}T)^{-1}$ is non-expansive for every $n \in N$.

Thus, associated with every accretive operator is another operator called the "resolvent" of T. This operator is denoted by J_n, maps X into D(T) and is defined by $J_n = (I + \frac{1}{n}T)^{-1}$. Moreover, $\|J_n(x) - J_n(y)\| \leq \|x - y\| \ \forall x, y \in X$. The following inequality relates resolvents to the initial accretive operator T:

$$n\|x - J_n(x)\| \leq \|T(x)\| \ \forall x \in D(T)$$

Indeed,

$$n(x - J_n(x)) = n(J_n(x + \frac{1}{n}T(x)) - J_n(x))$$

$$\begin{aligned}n\|x - J_n(x)\| &\leq n\|(J_n(x + \frac{1}{n}T(x)) - J_n(x))\| \\ &\leq n\|(x + \frac{1}{n}T(x)) - x\| \\ &\leq n\|\frac{1}{n}T(x)\| \\ &= \|T(x)\|.\end{aligned}$$

This result may now be used to prove that the J_n's converge pointwise to the identity operator on X.

Theorem 2: $J_n(x) \to x$ as $n \to \infty$.

Proof: For $x \in D(T) \cap R(I + nT)$, then

$$\begin{aligned}\|J_n(x) - x\| &= \|x - J_n(x)\| \\ &= \frac{1}{n}n\|x - J_n(x)\| \\ &\leq \frac{1}{n}\|T(x)\|\end{aligned}$$

which converges to 0 as $n \to \infty$. Therefore, $\lim_{n \to \infty} J_n(x) = x$.

Theorem 4, will further show that this convergence is uniform. For an example, the interested reader is encouraged to graph, on the same set of axes, a sequence of resolvents $J_n(x) = \frac{-n}{2} + \frac{n}{2}\sqrt{1 + \frac{4}{n}x}$ for the accretive operator $T(x) = x^2, x \geq 0$.

The proof of Theorem 4 involves a "resolvent identity" which establishes connections between each J_n. In particular, this resolvent identity shows that if one J_n satisfies a certain property (compactness, uniformly continuity) they all do. The main results are contained in the next two theorems.

Theorem 3 (Resolvent Identity):

$$J_n(x) = J_k\left[\frac{n}{k}x + \frac{k-n}{k}(J_n(x))\right] \tag{4}$$

where $J_n(x) = (I + \frac{1}{n}T)^{-1}(x)\ \forall\, n \in N$.

Proof: First, consider

$$J_n(x) = (I + \frac{1}{n}T)^{-1}(x)$$

$$(I + \frac{1}{n}T)J_n(x) = x$$

$$J_n(x) + \frac{1}{n}T(J_n(x)) = x$$

$$\frac{1}{n}T(J_n(x)) = (I - J_n)(x).$$

Now, consider

$$J_k\left[\frac{n}{k}x + \frac{k-n}{k}J_n(x)\right] = J_k[J_n(x) + \frac{n}{k}(I - J_n)(x)]$$

$$= J_k[J_n(x) + \frac{n}{k}(\frac{1}{n}T(J_n(x)))]$$

$$= J_k[J_n(x) + (\frac{1}{k}T(J_n(x)))]$$

$$= J_k[I + \frac{1}{k}T]J_n(x)$$

$$= (I + \frac{1}{k}T)^{-1}[I + \frac{1}{k}T]J_n(x), \text{ since } J_k(x) = (I + \frac{1}{k}T)^{-1}(x)$$

$$= J_n(x).$$

Theorem 4: J_n's are uniformly convergent on X.

Proof: It was previously established that $J_n(x) = (I + \frac{1}{n}T)^{-1}(x)$ with $\|J_n(x) - J_n(y)\| \leq \|x - y\|$. Furthermore, the resolvent identity established in Theorem 3 says

$$J_n(x) = J_k[\frac{n}{k}x + \frac{k-n}{k}J_n(x)],$$

so consider $\|J_n(x) - J_k(x)\|$ for $x \in X$.

BEST COPY AVAILABLE

Then

$$
\begin{aligned}
\|J_n(x) - J_k(x)\| &= \|J_k[\frac{n}{k}x + \frac{k-n}{k}J_n(x)] - J_k(x)\| \\
&\leq \|\frac{n}{k}x + \frac{k-n}{k}J_n(x) - x\| \\
&= \|\frac{k-n}{k}J_n(x) + (\frac{n}{k} - 1)x\| \\
&= \|\frac{k-n}{k}J_n(x) + \frac{n-k}{k}x\| \\
&= \frac{1}{k}\|(k-n)J_n(x) + (n-k)x\| \\
&= \frac{1}{k}\left|(k-n)\right| \|J_n(x) - x\|.
\end{aligned}
$$

Since $\lim_{n \to \infty} J_n(x) = x$, $\|J_n(x) - J_k(x)\| \to 0$ as $n, k \to \infty$.

This result implies that the "J_n's" satisfy the so called "Cauchy criterion for uniform convergence" and thus converge uniformly to the identity.

CONCLUSION

A sequence of non-expansive operators can be associated with each accretive operator T and that these "resolvents" converge uniformly to the identity. Future work could entail a detailed study of the resolvent identity and its relationship to "compact displacements" of the identity.

NUMERICAL MODEL FOR ICE MELTING IN A RECTANGULAR ENCLOSURE WITH DENSITY EXTREMUM EFFECTS

Makeda Smith

Faculty Advisor: Khoudir Medjani

Phase change phenomena are common, both in nature and in industry. The liquid phase can experience strong convection currents which can have a significant effect on the overall solidification process. Furthermore, water is unique in that it has a density maximum at 4 °C. Numerous studies have been published on ice melting and on convection of water around the density extremum. But very few studies have addressed both problems at the same time. The present paper applies a recently developed numerical model to simulate this problem, including the flow equations inside the liquid phase.

INTRODUCTION

The importance and complexity of melting and solidification processes has resulted in large numbers of investigations, both analytical and experimental. In nature, this situation arises during the freezing of seawater over large areas of the globe, and inside the earth during the cooling and solidification of magma bodies. In industry, examples include solidification of alloys, crystal growth, and freezing of food stuffs.

Natural convection has been shown to have a great influence on the solidification/melting process. This topic has been extensively studied in the last few decades. Generally speaking, it is an accepted fact that natural convection enhances heat transfer rate during melting but retards it during solidification (Kim, 1993). Because of convection, the interface between the liquid and the solid can be irregularly shaped and difficult to track in numerical models. Recently developed one-region models solve this problem by applying one single set of equations to the whole domain (Bennon, 1987). The goal of this study is to contribute to the general knowledge in this area by considering freezing of water in a rectangular enclosure in a situation where density inversion effects are important. The present paper numerically models this situation and the results are presented and explained.

DESCRIPTION OF THE PROBLEM

This study focused on a rectangular enclosure filled with cold water. The left vertical boundary is kept at a constant temperature of 263K, while the right side vertical boundary is at a constant temperature of 276K in the first case, 279K in the second case, and 281K in the last case. In all three cases the top and bottom boundaries are thermally insulated. These boundary conditions have been set to investigate what happens to the water circulation and the freezing of water before and after a density inversion is introduced. Unlike normal fluids, pure water exhibits a nonlinear variation of its density with temperature, with density increasing with temperature up to 4 °C and decreasing thereafter.

MATHEMATICAL FORMULATION

Momentum conservation in the x-Direction:

$$\frac{\partial(\rho u)}{\partial t} + \rho\ V\cdot\nabla u = \nabla\cdot(\mu_l\ \frac{\rho}{\rho_l}\ \nabla u) - \frac{\partial p}{\partial x}$$

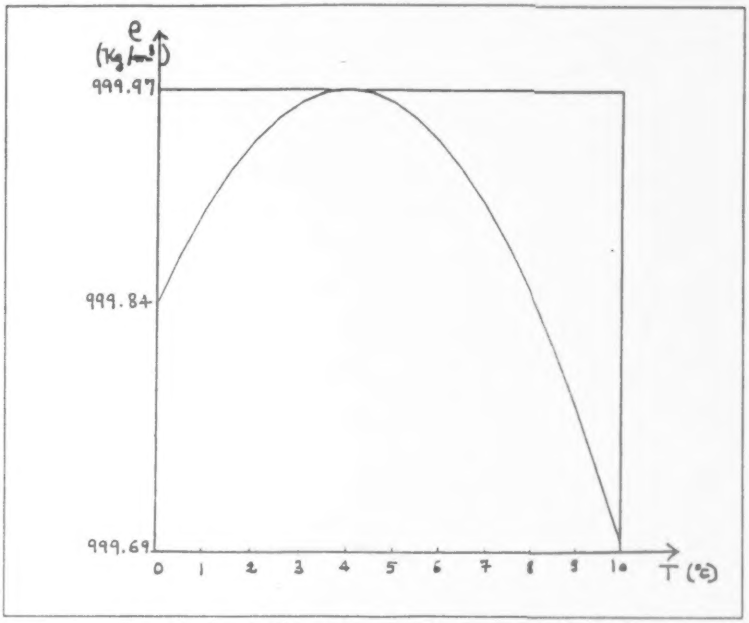

Figure 1. Density-Temperature Relation for Water Near 4 °C

Momentum conservation in the y-Direction:

$$\frac{\partial(\rho v)}{\partial t} + \rho\, V\cdot\nabla v = \nabla\cdot\left(\mu_l \frac{\rho}{\rho_l} \nabla v\right) - \frac{\partial p}{\partial z} + \rho g[\, \beta_T\, (T-T_r)]$$

where μ_l is the dynamic viscosity of the liquid phase.

Energy Conservation:

The energy equation is written in terms of the enthalpy h.

$$\frac{\partial h}{\partial t} + \nabla\cdot(Vh) = \nabla\cdot\left(\frac{k}{\rho c_s} \nabla h\right) + \nabla\cdot\left(\frac{k}{\rho c_s}\nabla\,(h_s-h)\right) - \nabla\cdot\left((h_l-h)\, V\right)$$

Where the subscripts "s" and "l" refer to the solid and liquid phases, respectively. When a given control volume is undergoing phase change, the percentage of latent heat released (or absorbed) will determine the liquid fraction in it. A liquid fraction of zero means that a control volume is entirely solid, whereas a liquid fraction of one means that it is entirely liquid. The locations where it is between zero and one then simply represent the interface. At any given time, the value of the enthalpy within each control volume is known. This in turn allows for the liquid fraction distribution to be calculated.

NUMERICAL ANALYSIS

The conservation equations are solved using SIMPLER (Semi-Implicit Method for Pressure-Linked Equations Revised), which was introduced by Patankar (1980). This method solves the x- and y-momentum equations given above directly for velocities. It uses a scheme that corrects the pressures at each time-step. The pressure corrections are then used to find an improved velocity field. Once a converged velocity field has been found,

other equations, such as energy and species are solved for using the Tridiagonal-matrix algorithm (TDMA).
Dimensionless variables are defined as follows:

$$r' = \frac{r}{H} \quad , \quad z' = \frac{z}{H} \quad , \quad t' = \frac{t\alpha_l}{H^2} \quad , \quad u' = \frac{uH}{\alpha_l} \quad , \quad v' = \frac{vH}{\alpha_l}$$

where the primed quantities are dimensionless, α represents the thermal diffusivity, ν the viscosity, and *H* is the height of the domain of study, which is equal 10 cm in this study.

RESULTS

The results shown are for several real time values ranging from 5000 to 15000 time steps. This range was important because it shows the important steps leading to the formation of uniform and nonuniform flow circulation. The temperature increases from the left to the right. The left wall is assumed to be at a constant temperature of -14 °C, while the right wall is kept at a higher temperature (3, 6, and 8 °C, depending on the case).
